The Editor is always gind to receive for examination illustrated articles on subjects of timely interest. If the photographs are morp, the articles fund, and the facts authorite, the contributions will receive special allention. Accepted articles will be paid for al regular space rates.

The purpose of this journal is to record accurately, simply, and litterestingly, the teath's progress in sever tife knowledge and industrial achievement.

#### Nature Completes the Panama Canal

THE closing of the states gates at the Gatun Spillway on July 1st may be regarded as the flux! step taken by our engineers in the great work of providing an artificial deep-draught waterway be tween the Atlantic and the Pacific. It is for nature to During the pext four months the turbulent Chagres River and the lesser streams of the Panami Congress server and the losser streams of the Panama district will pour their waters into a widespread valley from which there is no outlet. Shut in by the tatum Dam at the north and the upper lock gates of Pedro Mignel to the south, the surface of Gatua Lake will rise luch by inch and foot by foot. Its ever-wideling area will creep silently up the converging valleys until the lake has risen to its working level of eighty-five feet above the mean tide level of both oceans, at which a vast artificial inland sea of fresh water will have been formed with a total surface area of neath

one hundred and seventy square miles.

There is a certain flavor of poetry and romance in the greater works of engineering, especially in those of a civil character—as every visitor to the Capal during struction must have realized before he had g to construction must have realized nector are mad going very far over the work. There is something that appeals to the imagination and even to our sense of the dramutic in contemplating the thought that the Chagres River which at the outset of operation was regarded as the most serious problem confronting the canal builder, the most stubborn enemy to his prog-ress, is to-day his best friend, and under his guiding hand is putting the fluishing touch to this stopendou

Incidentally, in the harnessing of the Chagres River, our engineers will greatly facilitate their struggle against that other great natural obstnele to the Canal completion, the slides at the Culebra cut; for with the of the lake it will become possible to fic cut, and locate at the most troublesome point of sild ing the two extremely powerful dredges which are now approaching completion for the istimbut thank Comunission. These dredges with their monthly capacity of 2,000,000 yards will probably be able completely to control the situation and take out the sliding material control the struction and take on the strong materials as fast as it comes in, and at a cost far helow that possible with steam showers. Furthermore, their great capacity makes it certain that such sides as man from time to time occur during the operation of the Canal will never become so serious as to hinder the flow of

#### Reversing the Locomotive

THERE are some popular technical fullactes strongly entrouched in public belief that the survive in spite of reiterated contradiction.

Among these is the belief that the first thing a locome three does or one of the first when he sees that a collision is inevitable is to apply the brakes and

exercise an engine.

As a matrix of fact, we doubt if one in ten thousand of the locomoduse engineers of this country would be guitty of the aspundity of reversible libs counts would be guitty of the aspundity of reversible libs counted and applying his brates at the same time. There was a day in the earlier factors of sufficiently, after an engineer would have been smallered paints in his duties if he

did not in nh emergency reverse his engine; but with the growth of technical knowledge it has come to be understood that to reverse the engine after applying the brakes is to defant the very object for which the train brakes are applied.

train brakes are applied.

In justice to the early locomotive engineers, however, it should be remembered that only the tender of the horomutive carried brakes, not the engine itself; and under those conditions the reversing of the engine appiled an additional though comparatively small retard-ing effect, supplemental to that afforded by the tender

brakes. We refer to this matter in, conjunction with the in-telligent letter which we publish in our correspondence columns, from which it is evident that our editorial of June 21 is linkle to be inscensired. Aur reference to the necessity for quick control of the revealing gear was not intended to course, the idea that the Scizz-TIPIC AMERICAN advocated the reversing of the engine when the engine brakes were applied. In saying:
"Only a stop which would reverse the power would be of any service when air brakes proved inoperative at crucial moments," we were pointing out that should the air brakes fall entirely, as it is claimed they did in the Stamford collision, the only thing left for the engi-ueer to do would be to reverse. This would have some effect, though retardation due to the locking and sliding of the wheels on the rail w ould have an insignificant effect upon the momentum of the whole train.

The folly of reversing when there are brakes on the eughie and these brakes are set is evident if we remember that, when the engine is running with the brakes d, the retarding effect is due to the large gate aren of contact between the brake shoes and the trend of the wheels; whereas, when the engine is re-versed, the frictional area of the bruke shoes is replaced by the very small area of the sliding surfaces in con-tact between the tread of the wheels and the rails with the result that there is an immediate large reduc tion of the retarding effect of the engine on the trein behind it

#### The Problem of Marine Oil Engines for Ocean Liners

HE constructive optimism with is so valuable an asset in the development of new inventions frequently leads to their application on a scale frequently leads to their application on a scale which is not guaranteed by the actual practical development of the art. It begins to look as though the stallation of exclusive Diesel engine and other engine plants of large powers in bir ocean stemaships was a case in point. We say this with the full appreciation of the fact that the work of the German engineers in this direction has been both brilliant and marked by a lavish expenditure of brains, time and money. Although the leading build or large unrine oil engines are not discouraged, they realize that a large amount of research and experi-mental work must be accomplished before oil engines can be built in sizes much larger than the largest that are now in service. The difficulties are chiefly those which arise from s evere temperature stresses, and from

the complicated valve mechanism.

It is certain, then, that the large oil engine has b no means reached its flust stage of development; and we may look for some radical changes, particularly in the direction of simplifying the main constructive ele-ments of the oil cuglin, in reducing the number of its

mixed plant of steam turbines and oil engines mived point of steam turnines may on engines, susas, as a powerful oil engine on a central shaft with steam turbines driving the wing propellers.

Let it be clearly understood that the above is written

with the problem of the oil-motor-driven battleship and liner in mind. In the smaller powers the success has liner in mind. In the smaller powers the success has been so marked as to render certain a very large displacement of steam by heavy oil Furthermore, some of the problems which complicate the question of large pawer milts on the sea--say, of from 10,000 to 12,000 inter-power-are not so serious when the plant to deskined for stationary service on land; and here we have been a start of the rends there were services as the state of the rends there were services as the state of the rends there were services as the state of the rends there were services as the rends there were services as the state of the rends there were services as the state of the rends there were services as the rends there are the rends there are the rends there are the rends there are the rends that the rends there are the rends there are the rends that the rends there are the rends that the rends there are the rends that the rends that the rends there are the rends that the rends tha may look for a steady if not rapid increase in dimer slone and nowers.

#### Bombarding a Defense With Dirigibles

HE aspect of a huge rigid airship of the Zeppelin type, 500 feet in length, of 25,000 cubic meters capacity, capacity, capable (as ther soon will be) of attaining a speed of 70 miles per hour, carrying machinerums, both in the care below the envelope and on a platform on top, and transporting u load of 8 to 10 tons, with a range of action of 8,000 miles, and implying the menace of the release of half a ton or more of explosives at one "drop" on dock gath, remain; ship, is extremely formidable. When one of that the dirighble one travel at night, and grows with stop of engines over the target which is tended to destroy, the memore is more series and

There is, however, another side to the ass the first place these large atrables are vary to handle near the ground and once state; a there until they can return to their special sh cannot ride out a storm at anchor, but must elth to drive through it on their return from a vorage which is a risky proceeding if the wind is centrary, or they must drift and lose ground and be driven are away from their shelter. Their supply of freely in awny from their sheller. Iner supply of free initial, so that in either case they man have, to sin up, and once it is exhausted to are cooked to struction. If they carry explosive they have the their fuel reserve

Secondly, the airship, as an engine of war, and not Secondly, the airsulp, as an engine or war, and any merely a means of reconnolssance, has yet to present its value. Mr. Hudson Maxim declared some came said in a lecture to the Brooklyn Aeronautical Association. that a high explosive which should be so powerfur destructive when employed in aerial bombs as to to the expectations and predictions of the scarcemons. could not be made; even dynamite to do much Gamage required to be confined. The destructive power of shells d torpedoes is undoubtedly enormous d that the conditions are favorable, but great as the average man supposes, especially if he has been through a short course of blood-curding aerial fiction.

The effects of the battering of modern heavy navel guns on a battleship and its crew, as described witnesses on board Russian vessels in the Bass witnesses on board Russian vessels in the Russo-Jupaine en war, are impressive to a degree, but the shelfs in such a case are directed with anormous propulsive force from rifled gums against solidly resistant such curses of wood and metal, not merely dropped from a considerable height to the earth, among buildings. Experiments with dropped live shells and explosives have shown that while they might land within a remarkably short distance of the target, I was just had finkancy which made all the difference in the resulting demans, for the ofference of the residence and the same of the sam

that the damage, for the effects of high explosives are very local and the momentum attained by any heavy object failing from a considerable beight is such that it buries itself in the ground and the force of the explosion caused by a percussion fuse is thereby neu-tralized. This does not imply that bombardment from aerial machines would be entirely ineffectual, but 4f we may judge from the analogy of the results within ory of man of artillery practice against towns the memory of man of artillery practice against towns and villages, it would not be worth the expenditure of time, energy and ammunition, nor the riskt of life involved. Ladyunith stood the bettering affects of twenty odd thousand shells with practically no damages. Nimilar results attended the bombardment of the forter round Pretoria, and lyddite shells, though they dog cavities and made openings in the walls of the Pierrish fort outside Omdurman, did little or no real damage. In none of these cances was the bösinbirdusent damage. In none of these cases was the bembard a factor compelling the surrender of the garrison.

Thirdly, the dirigible is notoriously a large and very vulnerable target for artillers, if it should descend to within 5,000 feet. That it would be difficult to hit while going at full speed cannot be doubted, but it cannot while similar truit speece cannot be doubted, but it cannot make use of its superiority over the acceptance as a platform for bomb dropping, unless it stops its engines and hovers vertically over the target at a sheight well within easy range of the guns. It is difficult to believe that the most practiced board-droppes could bit any of the smaller buildings, otherwise than by chause, from a height of 5,000 to 6,000 feet, and the gunner would have a good opportunity of brinking down the

from a height of 5.000 to 6.000 fast, and the gunner would have a good opportunity of beinging down the airship while it remained stationary.

It may be presumed, therefore, that the efforts of the diracible would be confined to reconnaisance by day with a view to marking down certain points for statick by night. "Whit a favering wind and under cover of darkness the pilot would subsequently endeavor to place himself in a position to drift sliestly, with stopped engines, until approximately over the chosen larget, the bearings of which would have been ascertained by reference to the man, sided possibly by enginess and the same of the second process of t

erest .

\*\*Ecrossie Biectite Bisil Coaches.—Rix railroad oars ditiven by electric motors supplied with surrent frem kerosene electric generating sets are being built by the British Westinghouse Company; one for the Cuban Central Railway, one for the London Northwesters Railway, three for the Nordmark Klasselforens Januagaktebolag, Denmark, and one for the New Zealand government. The engines used are of the str-cylinder typn, having a bore and stroke of 5½ by 6¼ inches, respectively, and developing 60 horse-power at 1,100 revolutions per minute. Kerosene is used as fuel by vaporising it in a G. C. vaporiser which displaces the erdinery muffler. Geseline is used for starting purposes until the vaporiser is heated.

Dissel Engine Tewbost.—The new towbost.

purposes until the vaporiser is heated.

Dissel Engine Tawbeat.—The new towboat:
"Savois." which is in use by the Italian navy, is noteworthy from the fact that it is equipped with Diesel oil engines. Though its displacement is only 170 tons it carries a 280 horse-power engine of the four-cylinder, two-cycle type. It runs at 280 revolutions per minute, and is started or reversed by the use of compressed air at a comparatively low pressure. A compressed air tank on hoard carries enough supply to furnish sixty starting or reverse operations, and these are said to take but a few seconds. Owing to those advantages, the new corft is a remarkably these advantages, the new craft is a remarkably easy one to handle.

easy one to handle.

Wedding Copper with the Oxy-acetylene Hama.—
A process of welding copper with the oxy-acetylene flame has been developed by a German inventor named Carl Canzier. He has found it necessary to use larger torches than for iron welding, but in general the process is similar, except that he employs a liquid welding paste, and a special copper welding wire. The paste prevents the formation of oxido. The process has been used for welding copper plates up to an into in thickness. The weld will withstand soid and its strength is could be that of a continuous solid course. is equal to that of a continuous solid copper sheet. The process is being used in the principal copper works in Germany with great success. Device for Testing the Hardness of Steel.—A very

Device for Testing the Hardasse of Steel.—A very simple device har recently been invented for testing the hardness of steel by impact. It countsts of a tabular standard fitted with a hardened steel ball at 'the lower end, which is placed upon the steel to be tested. At the upper end of the standard is a spirit level by which the standard may be brought to true vertical position. Mounted, on the standard is a cylindrical drop weight. This is raised to the top of the standard and then dropped, striking a weight-receiving block at fift bottom of the standard, which communicates the implect to the steel hall, and makes an indentation in the steel that is being tested. By measuring the diameter of the indiant-vicks with a celluloid scale the hardness of the steel tested. By measuring the diameter of the indicate tion with a celluloid scale the hardness of the stee - bonimed

may be determined: Ramburg:—As natural gas does not occur frequently in Garmany, the example pointed out by Dr. Strache of a gas well at Neusnaman and Strack of the Hamburg region, is secritly of resnark. The gas leaves the ground it help frequently in the Hamburg region, is secritly of resnark. The gas leaves the ground it high piecestry, showing 30 amoughness, it is said. The city of Hamburg leaving to make use of the gas, and is at precision beingsed in larging a pipe line in a to bring it for the several gas words, shows it will be mixed with could gas, to as to bring it for the supply off like he used in the copyright of the second of the gast well fined, and this will be several as the gast well fined, from secondary of this second is precised in delication; statical, and this will be several as the gast well fined.

The Weifure of University Students.—The Congress organized by the National Union of Students Associations was held at Paris during the month of May and was an eyest of considerable interest and numerous matters tending to promote the welface of university students were discussed. What is known as the International Pederation of Students is now being organized, and is intended to bring students of all nations into doner relations than before,

The Death of Fref. Verneuil.—We have to record the decease of the French scientist Verneuil, who occupied a leading position as professor of glass-making and ceramics. To him are due many interesting researches and practical methods in various fields. In connection with M. Wyrouboff, he carried on productive researches upon thorium and certum, and he acquired some colebrity for his work in artificial production of the ruby as well as in manufacture of optical glace.

The Congress of British and French Electrical Engineers.—An interesting event was the Congress of British and French electrical engineers which was held at Paris May 21st to 25th, on which occasion numerous members of the British Institution visited the capital and took part or the Britain institution visited the espital and took pair in the conferences, visits and receptions organized by the home institute. Papers were read upon electric traction, power production subjects and others, and the delegates visited the St. Denis and other large city plants, the visited the St. Denis and other large city plants, the Metropolitan sulpray and electric stations and various points of interest. M. Georges Claude gave a lecture upon luminescent tubes (neon tabes, etc.), and Com. Ferrie upon wiredows telegraphy, with special reference to the Riffel Tower plant. After visiting Versailes and the Bue seroplane grounds, the members returned to Paris by the effectie railroad. On the whole, the visiting members were quite pleased with their stay at the capital.

The Ascent of Mt. McKisley.—On June 7th, Archdesson Hudson Stuck, accompanied by Robert G. Tatum, Harry P. Kerstens and Walter Harper, reached the top of the south peak of Mt. McKisley. Barometric observations which were made by Dr. Stuck as said to indicate that the height of the mountain is 20,500 feet. The oxide the McKisley carly in McKisley carly in May, but was telaked to reach the Spmuit of Mt. McKisley carly in May, but was telaked three weeks in cutting a May, but was ticlayed three weeks in cutting a passage three thiles along ice, thrown across the ridge last summer by an earthquake.

ridge last summer by an earthquake.

The Casadian Arctic Expedition was definitely begun on June 17th, when the whaler "Karluk," commanded by Capt. Bartiett, and having on board ten of the scientific staff and a crew of fitees, sailed from Victoria, B. C. The leader of the expedition, Villishianus Steffanson, expectate to join the party at Nome, Alaska, about July 20th. At Nome, the expedition will divide into two sections, one of which, under Steffanson, will sail morth in the "Kartik" to seek the unknown lands supposed to exist on the poleward side of the Beaufort See, while the other, under Dr. R. M. Anderson, will proceed westward is the small suntilistry gasoline schooner "Alaska" and will endeavor to reach a base in southwestern Victoria lasad, from which point extensive explorations and investigations will be carried out. (Some preliminary plans of the expedition and a chart showing the proposed routes will be found in the Scientwister Camerica. SCIENTIFIC AMERICAN SUPPLEMENT of May 3rd,

Further Results of the Mawson Expedition.—
The experiency and schewements of Mr Frank Wild and his seven companions, who formed the second base of the Australasian Antarctic Expedition, have just been made public. After leaving Mawson and the main party at Addie Land, the second detachident sailed westward along the Antarctic coast, under orders to form a base on Sabrina Land or Knox Land. The farmer land was found not to crist, and ice prevented access to Knox Land. Finally the party was ianded. vas found not to exist, and toe prevented access to Knox Land. Finally the party was indeed to Knox Land. Finally the party was indeed to Knox Land. Finally the party was indeed will think was missisten by Wilkes for "Cremination Land," It was named "Shackloton Giseler." From this base surveys were made all along the coast from 101 degrees east longitude, on the east to the point reached by the German expedition of 1902 on the west, besides possertating inward—in one 918ce 50 miles. The main robust of these explorations was the discovery of a treat of land having 350 miles of coast, and probably estending, septit to the pole, which the explorers comment. Was present the pole, which the explorer polecy of Emperor penguisa heretelyors recorded. Some 7,000 young Emperor being was found to the exposition of the expedition's basides innumerable ordinary; penguing. The Mawon expedition as a whole; may be east to have requised in the accurate designation of about 1,000 miles of new coastline.

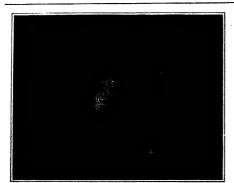

A Lucky Escape from a Hall Storm.—The Chalons district for twenty miles around Vitry le Pranços experienced a terrife hall storm early in the evening of May 9th. So violent and lengthy was the storm that the ground was covered to a depth of several indices with hall stones Many persons were injured and two military aviators who were returning from Rheims raced with the approaching storm and landed just as it broke. The aeroplanes were badly damaged by the hall and one of the pilots was indamaged by the hail and one of the pilots was injured. Although an aeroplane can fly in a pelting rain, it is doubtful if the machines in this instance would have descended safely if they had been ove taken while in flight by the hall storm.

Morean Anonymously Assisted.—An anonymous contribution of \$2,000 was lately received at the National Aerial League, at Paris, in order to enable Engineer Moreau to proceed with his accoplano method, in which he secures a remarkable stability. The value of his invention is now beginning to be recognized, but although he was able to proceed with his work by the aid of a private subscription, he was obliged to stop when this became exhausted. However, the French army is likely to take the mat-ter up soon, as it is claimed that the Moreau acroter up soon, as it is elaumed that the Morean aero-plane realizes a complete automate stability. In a recent flight made by Lieut Sulmer, the aeroplane was able to fly for 35 immutes in rather rough weather without having the pilot operate any of the steering parts. As M Morrau said he would do, he made the entire flight with folded arms, which appears to be a remarkable feat.

Sahara Flights.—A very successful aeroplane flight over the flosert of Sahara was recently made by four Farman biplanes mounted by French army pilots. What is noteworthy is that the trip, covering about 500 miles distance, was made above the desert region 500 miles distance, was made allow the desert region where any kind of aid is impossible. Starting out from the military aeroplane post which was recently established at Bakra on the edge of the desert and in the Algorian region, the party proceeded with the object of making the flight to Tonggourt, a miles of the ones, and thus military station lying in one of the cases, and was done very easily by the whole party. Then the return trip was made without any mendents, clearly showing the value of the scriptsen in making communication over desert country. As the es a number of military posts Fronch army possesses a number of initiary posts in the regions of Algeria and Morocco, the acroplane is certain to be of great value in the future in making a rapid connection

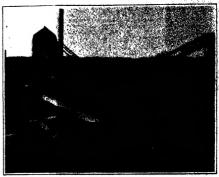

Instruments for Aeropiane Research .-- At the recent Royal Society Soiree, Mr Mervin O'Gorman exhibited numerous instruments used in aeroplane research. Two of these were instruments for measuring the tautness of wires employed in aeroplane and airship construction. The principle of both is and airship construction. The principle of both is the same, one being somewhat larger than the other and reading to higher stresses. In these meters the and reading to higher stresses. In these meters, the wire is passed over three points out of alignment, the middle point being connected by a lever with an indicator. If the stress ou the ware necessary, the middle point to strawn in and the movement is shown on a dial calibrated in pounds or torus. The motor has to be calibrated before actual use on seconation wire, by means of suspended weight aeronautic wire, by means of suspended weights It has been shown by its use during flight that the It has been shown by its use during high that the load that comies on the wires of aeroplane wing framing is often actually twee the dead weight loaded on the wire. The instrument is especially in-tended to show the variation of stresses during flight

The Mackay Army Aviation Cup. -Mr. Clarence II Mackay has presented to the Wm. Department, through the Aero Club of America, a large silver trophy to be competed for by the military airmen of the United States Army in a series of regonnas-sance competitions. The first of these was held at same compenious and on October 29th, 1912, and was won by Second Lacut Henry II Arnold of the Twenty-muth Infantity. No definite date has been set for future competitions. The competitors must fly on the same day if practicable, after hav-ing been notified two weeks before the event. The ing been notified two weeks neduce the event. The tests are to be passed upon by a board of five judges. The highest average rating obtainable will be 300 points, which allows 50 points for each of the six events. The tests include accuracy of location, accuracy in estimating troops, character of written report, time of recomassance, altitude re-quirement and landing accuracy. The height average is put at 1,500 feet. Any competitor dropping below 1,000 feet will be disqualified—this because below 1,000 rect will be disquarined—this obsculate flying at low heights would be suesdail in actual warfaco. Mr. Mackay's cup is of solid silver, thirty inches in height, and stands on a block of Circas-sian walnut. On the rim at the top of the cup are the figures of four women holding in their out-stretched arms four small aeroplanes of the hiplane

Coke ovens with bins and washery, showing enormous development of smoke.

Masontown, Pa.

General view of a retort coke even plant of large dimensions and favorably situated.

## The Beehive and By-product Oven in Coke Production

C OKE is produced by three methods: In the beehive coke oven; in the by-product oven; and as a by-product of gas works. The last being spongy and unsuitable for metallurgical purposes need not be considered any turther.

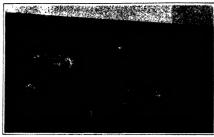

Millions of tons of metallurgical coke are annually consumed in the United States in the manufacture of Irou and steel. This coke must be deuse and firm so as to sustain the superincumbent charge in the furnace without being crushed; it must also be substantially free of subhur

From the simple of the beeblive oven the origin of the name is apparent. In this over, the cold is coked by the burning of the gases evolved and a part of the charge produce also in a simple of the charge produce about airty-flyer tous off cold-distillation inclusive of ter and ammonia having been burned in the coking process. The sames and soot artising from a beshive oven plant create such a missaice that no city would tolerate it in its telicity. While the process is wasteful, it is still able to survive against the competition of the by-product coke oven because of the small capital required for its installation. The coke produced is of excellent quality.

The hy-product over obsit requires the investment of large capital, but its operation is much more economical, moreover, the sancke unbource is absent One handred tons of coal will produce about seventy-five tons of coal, one thousand gallous of sulphate of aumonia, and four handred and fifty thousand cuble feet of limitanting saw. The tar and ammonia operation and interest on the capital invested. It is therefore evident that the days of the beshive over are numbered in dermany, the bective oven was replaced by the by-product over years ago.

The greater part of the Huminating gas of the by-product own goes to waste except where the plants are located within a reasonable distance of large cities which can use the gas. Any returns from the gas are an additional gain to the by-product plant. We may look therefore for a further reduction of the palce of gas in some of the favorable situated cities

some of the favorativi stimuted cities. Bituminous coal is used for cocking, but not all of that kind of coal ts suitable therefor. It is necessary that at the proper stage of coking, the particles should soften and cohere, and form after coaling, a solid mass. Becomity the difficulty of non-coking coals has been overcome. When distilled gason, which consist mostive of hydro-carbons, are passed through no incandescent charge offices, they are 'cracked,' that is, the more complex mole complex mole

Building a bechive coke even.

Interior of condensing house of a retort coke oven plant.

The traveling structure on the right is the quencher, into which the hot

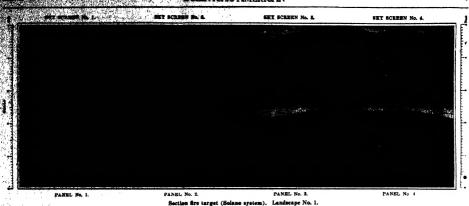

cutes are broken down to form simpler, hydro-carbons. In this breaking down process carbon is split off from the molecules and deposited between the particles of the lucandescent charge. The carbon atoms at the moment of their deposit have the peculiar properly of binding the particles of the charge together; the name "cementitions" carbon has therefore been given to the material thus deposited. At the same time the cote is earthed by this deposit of pure carbon. The silvery gloss of coke is due to this carbon deposit. Where the distilled gases are first passed through gas washers before passing through the incandescent charge, the tar and ammonia may be recovered.

The operation of the coke oven, whether beehive or by-product, is intermittent. After charging the coking chembers with coal, heat is applied to coke the same. Is the beehive oven, as stated above, combustion within the chamber itself furnishes the heat; in the by-product oven heat is applied externally to the retort by the combustion of gash in the besting fuses located in the heating walls between adjacent retorts. When the coking is completed—after 48 to 72 hours—the coke is quenched or couled by spraying water ou it, or in airtight receptacles. This method furnishes a superfor coke

Necestry coke roress have been constructed in which the coking operation is continuous, coal lieing fed into the retort at one sud and quenched coke coming out at the other. The "green" gasee distilled off at the forward end are made to pass through the incandescent charge at the rear end, thus enriching the coke and binding its particles together.

The specific gravity of coke as compared with coal is low. This is due to its porosity caused by the excepting gas during coke ing. But when the coke is compressed yithin the retort, after the volatile matter has been driven off, while it is still plastic and before it becomes incendescent and befure it becomes incendescent and brittle, a very dense coke resembling anthractic is the result. Such anthractic is now produced on a commercial scale.

There are two objections to the use of bituminous coal: One is the smoke nul-sance, the other the poor utilization of the hydro-extrone when burned in the ordinary furnace. When fresh coal is thrown on the fuel bed, volumes of smoke and gases are generated, whose combustion is incomplete. Not only are these gases lost, but their generation absorbe quantities of heat from the fuel bed. Becent methods have produced a smokeless fael by subjecting bituminous coal to a partial coking operation. The coal is heated in rectors at a comparatively low heat, 800 to 1,000 der. Fahr., which expels the beavier, smokely-ordening hydrocarbons, and readers the coal thus treated smokeless. If the work problem is solved and the congettioner's discovering the coal ten and smokeless. If the work problem is solved and the congettioner's discovering the coal ten and smokeless. If the

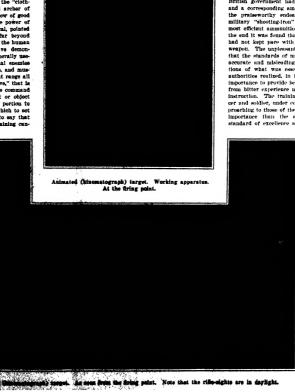

# Teaching Soldiers How to Shoot

How Artificial Landscapes and Moving Pictures are Used

By Major H. Bannerman-Phillips

TiME was when the soldier was instructed to Trearrie his dre until he could see an enemy's features distinctly, when the range at which the coursey of the fireturn of the infantry soldier could be relied upon with anything like reasonable certainty did not encode that of the 'entry park shear,' Truly speed by a trained because of the days of administrative rates and the state of the days of administrative rates and the state, the power definition to be proposed to distinct the proposed to distinct the relief of the days of administrative rate entries the content of the distinct of the proposed to distinct on the desire of the desire of the distinct of the proposed to distinct on the best distinct of the rife. This is not to say that men with good eyesight and sound training cunnoth it the mark at much 1 o ng er distances. The idea is merely that for practical

distances. The creative is the result of the series of the

stendy picked shots on the British side kept a much superior number of Boers lying down in their shelters for three days, so sharp and unerring was their fire.

For half a century before the Rose was the British government had expended much energy and a corresponding amount of public mone, in the prelawority endeavor to evolve the best military "shooting-tron" in the world and the most officient ammunition to nee with it, and in the end it was found that the skill of the soldier had not keep pace with the impresement in his weapon. The unplessant truth was officen home that the standards or military shooting were inaccurate and misleading, based on false conceptions of what was essential to efficiency. The authorities realized, in fact, that it was of less importance to provide better rifes than to evolve from bilter experience more suitable methods of instruction. The training of the holdvidual officer and soldler, under conditions of visibility approaching to those of the buttledeld, was of more importance than the achievement of a high standard of excellence at marks which could be

ly distinguished from their sur-roundings. So far did the average skill of the marksman lag beof efficiency of the really excellent weapon which he carried, that it was estimated that about fifteen hundred rounds of ammuduring the Boer war for every man struck on the enemy's side. Much of this waste of ammunition-in fact, probably three fourths of it-was enracy of aim, but to the misdirected, that is of the battlefield where the enemy was supposed to maining fourth was expended in shots which were true in direction, but fired with the sights of the worns elevation, owing to error in judging the runge. Then again the greater number of holdes which did not find their billier at ranges under 600 yards were probably wasted, because the men tries under conditions which do not obtain in power time, annuely, that the firers were themselves under fire, annuely, that the firers were themselves under fire, annuely, that the firers were themselves where the head down, and frequently because they could see no enough at which to direct their fire, atthough they heard bits missilest strike near them and whis host direction of the strike their directions of the strike their directions of the strike the strike their their directions of the strike their directions of their directions of the strike their directions of their directions of the strike their directions of their directions of their d

Failure to distinguish the target and Jodge the range, difficutities which often go hand in lound, are harder to deal with than want of accuracy of aim at a visible turget, and it is against three difficulties that hondern methods of tostraction in ritle shooting are or should be directed. The purpose of muskery training should is in the first hostnare to make the individual soldier in the first hostnare to make the individual soldier in the first hostnare to make the individual soldier in the first hostnare. His, coversant with the power of the weapon, and confident in his own skill give the tender of the second profile and judgment. He should use the intrader so as to give line best results for his own skill. His leaders and he should alike be capable of should go accurately at a given object, and able to recognize and describe any objective or target against which ritle-fire may require to be directed on service, and to Judge the distance to it from their position at the time. Finally, he should sugget self-control, and cheerbully und he telligently submit to the necessary fire-discipline executions of the cummunder who directs the first, and whose closely is leaders who are capatitived with the inter-tions of the cummunder who directs, and to long-time solves, but in cuncentrair their attention on the objects, and to be attained, select the targets in order of lang-trainer with resurd to hose objects, and direct and control the first of het first instance, and become experts in handling at the inter-time to the standards, to the end that they direct the large of the should be corried.

Besides being able to shoot steadily and accurately when there is ample time to take aim, a mate must be prepared to fire with or without the bayone fixed, at moving objects, and to ret to several shots in rapid succession with undiminished accuracy at cavairy charging, or to repel an attack at close quarters or a result of savages. He must further know how to allow for wind, and how to take advantage of every kind of cover while firing, so as to expose binneft as full time as besides to the view and fire of an enema.

Much of the mechanical partion of the training can take place indoors, on the barries-country and on the rifle rause. Muscle exercises to strengthen the special muscles brought into play, along trigate-proceding (a most important dotail and connected with breathing), firing standing and kneeling, dring proon, firing attituding and kneeling, dring proon, firing attituding and kneeling, dring proon, firing attituding and kneeling, dring proon fring attituding and kneeling, dring proon for each tensity of the standard process of th

Various ingenious devices have been invented to meet the need for visual (raiding away from the rifle range, and the vicinity of the bacracks, without involving the necessity for fedging distance practice and firing over large stretches of country, for which line and opportualty may be brasely wanting.

Among those are the various "lambeaue" targets and the kinematograph or salmated target. The "fluid-seque" targets represent typical stretches of country all the control of the country and the kinematograph or salmated target. #### Photographing Under Water

In the Scientific American for April 4th, 1108, we justifished an illustrated description of an apparatus decised by (2. Williamson of Norfolk, Va., for carrying on operations under water. The apparatus was designed to take the place of the ordinary diving outfit. Broadly considered, the apparatus consists of three pariets: (1) a fouting vessel of my suitable design; (2) a submerdable terminal operating chamber in which the work is carried on at the hortom of the water, and (3) in collapsible flexible metallic tube connecting the vessel and the terminal operating chamber.

Various types of terminal chambers are used, dependbux upon the class of work to be curried on; but usually the equipment of a terminal chamber consists of tools operated by compressed air or electricity, and mechanical sleeve extensions with aftached mittens, in which a labover may slip his arms and perform his work. The collapsible tube communicates with the atmosphere, so that the labover may perform his work under nonmal atmospheric pressure and therefore much more roovendentity than would be possible if he resorted to the usual diver's costume.

This apparatus was recently used in Hampton Bunds on make the submarine photographs which appear on the front page of this loone. The tube and work chamber were lowered from a thirty-foot barge through a well six feet square in the bottom of the barge. To take the under water pictures a funnel six feet long with a two-foot six-inch glass port at its large outer and was botted to the work chamber. Mr. Williamson's son descended into the work chamber with no ordinary cunera. A frame containing a reflector and a battery of electric lights, sagressating 1,000 candisatively of lectric lights, sagressating 1,000 candisatively and the same around the port. Section after sealment that the same around the port. Section after sealm of the tube was added nuttle the work chamber had reached a depth of thirty feet. Photographs were taken at that depth. The apparatus was then raised to intermediate depths and more exposures made.

Daylight tests were conducted which proved that at depths between ten and fitneen feet photographs of passing she had objects could be made with exposures varying from 1/10 to 1/15 of a second. The water in Hampton Roads is not very clear, but the experiments showed how much could be accomplished in submarine photography, in the clear waters of tropical regions with an asparatus especially designed for the purpose.

#### What Are the Ten Greatest Inventions of Our Time, and Why?

#### A Prize Article Contest Open to All Scientific American Readers

THE November Magazine Number of the SCHETTIFIC AMERICAN Is to be devoted in part to a review of the screen investions of our time. Because a targe number of SCHETTIFIC AMERICAN readers are either inventors or success of hivestions, it seems to the Editors that their judgment of the inventions produced in our time which descrive to be called the greatest, their appurisal of the relative importance of the paramount technical encilevements of our day, would be of peculiar value and interest. Therefore, it has been decided to loave the entire subject to them.

The publishers of the Scientific American offer three prises of \$150, \$100 and \$50, respectively, for the three best articles on the topic, "What Are the Ten Greatest Inventions of Our Time, and Why?"

Contestants for the prize must observe the following

- Each article must discuss and answer the following three questions:
- a. What, in your estimation, are the ten greetest inventions produced within the last twenty-five years. b. What are your reasons for this selection? Justiff your selection in each case.

o. To what person or persons to the greatest credit due in the developing and perfecting of each invention which you have selected?

- the in the developing and personning or sean investment which you have selected?

  2. The entire subject must be powered in a trypwritten article not, exceeding 2,500, worth in length, and must be treated as simply, haddly and sen-sechnically as possible.
- and must no honoline intentions of the intentions of our time, the contestants are limited to mischines, devices and discoveries commercially introduced in the last twenty-five years.
- 4. Since the Schenying American is "the weekly journal of practical information," and its resider perchability of the articles submitted school deal only with patentable inventions and distinct of the patentable inventions and distinct of the patentable inventions.
- covering.

  5. In order to guide the contestant in shedding what is a great plouser lawestion of our thas, it is suggested that practical success and special subgliques to manifold that practical success and special subgliques to manifold be used as a test. A modera discovery may have been suggested long ago and fill undestying theory even worked out mathematically, as in the case of wireless telegraphy, but herectakes it falls which could make the set tolerably, but here there is the discovery manifold under the set tolerably, but here there is the countries of the set tolerably due to make the set of the set
- 6. Contestants must not disclose their identity. Each article must be signed with an assumed name and must be accompanied with a sealed envelope, on which the assumed-name is written, and in which the resi name and address of the author is contained.
  7. Contestants must address their articles, accom-
- 7. Contestants' must address their articles, accompanied by the envelopes containing their real names, to "The Invention Contest Editor of the SCHENTIFIC AMERICAN 361 Broadway New York of The Technology New York of The Technology New York of Technology
- American, 361 Broadway, New York city."

  8. The articles will be passed upon by a Board of Judges, whose names will be announced in a future large of the Screen Advanced in a future
- Source of the Scheritzic America's.

  9. The Board of Judges will receive only the artithes submitted, the survelopes containing the true names
  and addresses of the authors will romain in the possession of the Editors of the Sourchies America's.
  When the judges have made their decision, the Editors
  will open the envelopes of the winning contestants and
  notify them of their success.
- 10. The decision of the judges will be announced in the SCHRITZIO AMERICAN of November 1st. 1918. The prise-whuning articles will be published in the order of merit in consecutive issues of the SCHRITZIO AMERI-CAN, beginning with the issue of November 1st. 1918.
- 11. The Editors of the Schrifted American reserve the right to publish in the Schrifted American or the Scientific American Suprement articles which have not been awarded prizes, but which are deemed worthy of homorable mention.
- of homosome measures.

  12. While contestants are not required to supply pictures with their articles, illustrations will be weitered.

  13. While wavings are submitted, they need not be elaborate; the staff artists of the Schrifter American will work them up for reproduction, provided the material supplied is intelligible. Do not send pictures torn from books and periodicals; they cannot always be reproduced satisfactority, and their unauthorised reproduction may constitute a copyright infragement. If photographs marked "copyright" are sent, they should be accompanied with the copyright were's written permission for their generoduction.

  13. Members of the staff of Munn & Company, In-
- 13. Members of the staff of Munn & Company, Incorporated, publishers of the Scientific American, and of Munn & Company, solicitors of patents, are excluded from the contest.
- All articles will be received up to 5 P. M., September 1st, 1913.

#### To Protect Iron Pipe

I RON pipe can be protected from corresion by heatling in a muffle to 1,000 deg. Fahr. and admitting steam at the same tamperature. A layer of magnetic oxide of iron is formed. A more astisfactory protection, however, is obtained by finishin process. The wellcleaned pipe heated to 700 deg. Fahr. as dipped into a mixture of pitch, coal are and a little impreed oil winish has been heated to 500 deg. Fahr. after a few mixutes the pipe is decided vertically and cooled. Of course the regiod oxidation of the itemped oil, former, at lough hinder, as in paint drying. Lead-deed, pipe in used for many purposes.

#### Price Cutting and Trust Control

To the Editor of the Scientific American:
The small dealer cannot afford to out prices; he must sell his goods at a fair profit. The large dealer who outs prices on standard goods for which a demand has been created through national advertising, does not do so to sell these particular goods but to attract trade to his store that he may sell other goods at a

trade to as searlarge profit.

This very thing is favorable to trust control, for by
outting prices the small dealer is gradually frozen
out. There are many other reasons why prices should
be maintained, but to my mind this is the most important.

#### Barb Spikes for Rails

To the Editor of the SCIENTIFIC AMBRICAN:
In your issue of June 7th I take interest in your article on "The Screw Spike Versus the Cut Spike." article on "The Screw Spike Versus the Cut spike."

I can readily agree with your argument against the present type of out spike. In one of your lituatrations I notice the position the split wood is forced to take; that is, a downward position from the drive of the spi e into the tie.

Now. If the cut spikes had barbs, such as on a fish hook, would not the swelling of the wood by rain or the like tend to make the wood take a position between se and greatly increase the resistance of the mid spik

Now, with the screw spike as you filustrate, could not a wrench of some sort be put on the head of said spike, and the spike be removed by train wreckers or Of course, without the threaded lining in the tie, this would be a much more difficult task.

In my opinion, I think there is need of consideration and debate along that line. Thomas H. Thomas

#### Fixed Prices and the Public

To the Editor of the SCIENTIFIC AMERICAN:

In the corset trade any manufacturer who can secure a large volume of business can manufacture at much less cost than if he has but a small volume. We know ioss cost than if he has but a small volume. We know of no way of setting large volume that compares with the policy of sequiring a national reputation by ad-writing and by quality for the trade-macked actide, and then fixing the retail price of that article so that all retailers who sell it, whether they be large or small, shall be protected in their profiles. The fact that the American corest manufacture is giving the ultimate consumer better values than any other corset manufacturers in the world, speaks for the soundness of this policy—of establishing a, trade-mark and maintaining

So far as corsets are concerned, there is no qu So far as dorsets are concerned, there is no question but what the cost of living has been reduced by the rigid system of price maintenance that is enforced by all the leading corset manufactures in the. United States. If prices should not be maintained, the large manufactories would become small, and the values that the women who wear corners would get for their money would be considerably less.

(The Wassian Brottman Company.)

Bridgeport, Conn. -LUCIEN T. WARREN, S

#### Baversing the Loos

To the Editor of its Strussyry Assumcas; I have been reading with much interest the fiscussion by the two reasons rathey accommands stop devices in your very validation paper. I find, however, in your district, the Need of an Automobile finite, in James dated June 21st, that a papelle bey received upperform to expressed from relationships the production of patients as expressed from relationships of the two productions.

You infer that the inability to reverse the engine was in part responsible for the collision at stamford on the New York, New Haven, and Hartford Railroad on June 12th. This is erronealthough it is believed quite generally and nginemen themselves who have not learned

by engiasemen themselves who have not learned from experience that to try to stop a locumotive by reversing the engines is utter folly. It is of course obvious that when once the cohesion between rail and drivers is destroyed there can be no further effect of retardation from the 'drivers. When the locomotive is pulling a train at even a slow speed over well sanded rails, if the engines are quickly reversed the inevitable result will be to slip the drivers, and this imme-diately destroys practically all of the cohesion. In she dryamometer are abbind an engine which

In the dynam meter car behind an engine which vas pulling a heavy train I have frequently ob was puling a heavy train I have frequently ob-served the drawbar pull drop practically to zero when the drivers were alipped, the reverse leven not having been touched. I have seen the cohe-sion drop from 40,000 pounds to zero without the position of throttle lever or reverse lever having been changed. If the reverse lever had been thrown over to tweese position and the engines reversed against the momentum of train, the result is obvious.

From current newspaper accounts. and no doubt inaccurate, it can be gathered that the engineer in question did succeed in throwing the eigeneest on question an surceed in arrowing over the reverse lever, which if it be true is merely additional evidence that he was wofully inexperienced. As to providing a more casily operating reversing gear, this has been done for several years on the very heavy locomotives in the form of a pneumatic reverse, which can be operated with less effort than even the throttle, but it is provided for comfort in landling the locumotive, and to advocate it for a safety device is absurd. The final conclusion that "only a stop which would reverse the power could be of any service when airbrakes prove inoperative at the crucial moment." is based on a false premise, and its application would offer no solution to the problem and would, in fact, be not near as fessible a plan as the various types of automatic stop aiready proposed, when airbrakes are operative.

Buffalo, N. Y.

W. L. Heinz. over the reverse lever, which if it be true is merely

#### Prices and the Ultimate Consumer

To the Editor of the SCIENTIFIC AMERICAN:

To the Editor of the Scientific America's: I have just finished reading a copy of the Supreme Court's decision in the case of Bauer & Cis and the Bauer Chemical Company v. James O'Donnell. In the writer's opinion we should not criticize the court in its decision. It is in no way responsible for the law, and that is where the main difficulty lies. Therethe law, and that is where the main dimensions. There is a chance for an honest difference of opinion regarding the scope of the word "vending" as incorporated in our patent law. The broad view of this term would our passat is. I us broad view of this corn within lead one to believe that vending of a patented article should be construed to cover the sale of an article or commodity from the manufacture to the ultimate consumer, regardless of the number of so-called middleer, regardie men it passes through.

e courts hold, however, that the vending of the The courts hold, however, that the vanding of the acticle, insofar as the manufacture was concerned, ceased when it passed into the hands of the desler or resulter. The point of differences is that of vending for results and vending for use. Our patent law should be changed so as to clearly cover this point and to bring such a change about. Manufacturers of patent articles handling their commodity through deslers and retailers should bring forcibly to the attention of our legislative hodies the danger to manufacturing concerns if the law is allowed to stand as at present interpreted. Shoukholders and employees of such con-

concerns if the law is allowed to stand as at present interpreted. Bonchholders and employees of such concerns should not overlook the fact that their interests are at stake, and should join with the manufacturers to bring about changes in our patent law to conform to the modern methods of merchandleng. Unfortunately, our logislatures are made up largely of men of little business experience, and their judgment in such matters is based upon theory rather than practice. These men are no doubt prompted by folly mutuve in their attempt to protect the "common people" of our country against the suc-saled monopolies. They unfortunately pick out a few glaring examples of abuse practiced by concerns halft on patent rights, and us these as criterious in their effort to regulate business of this hakers. Their main atm, of course, it to protect these as criterious in their effort to regulate business of this haster. Their main aim, of course, it to protect the weak against the strong; they, however, in strving to accorpilish their od, are weak-ning the strong rather than strengthening the weak; in other words, they are using distinctive instead of constructive methods in their statesprad solution of this problem.

In this case in question, to wit, the taking away from

sufacturer the ability to establish the reprice of his product will work not only great injury to the manufacturer, who has spent large sums of money in bringing before the public the merits of his goods, but will effect in the writer's opinion a result diametrically site to that intended insofar as the small retailer

and ultimate consumer are concerned.

This same point is covered in one section of the proposed Oldfield bill, now pending before the House, which if passed will create a chaotic condition in the business world where commodities are handled through dealers or retailers. When our original patent law we framed, it was not necessary to cover this point in question, as there was little heard of the indelleman in those days, the sales being largely made directly from manufecturer to consumer, and this difficulty manifests steeff in many of our laws in relation to business. Join in other words our laws have not kept dealers or retailers. When our original patent law s to-day; in other words, our laws have not kept pace with the changing methods of doing business. This fact has made it necessary for our courts, in in-terpreting a law as it pertains to present-day business. to read into them words or phrases, thereby adapting them to modern conditions, but in so doing have assumed the roll of lawmakers rather than acting in a judicial capacity as intended. In reading into the Sherman Anti-Trust law the word "reasonable," as applied to raint of trade, illustrates this point.

The writer's contention is the vending of a commodity does not stop with the sale from manufacturer to agent or dealer, but is still in the vending stage until the ultimate consumer takes possession, and, therefore, the manufacturer should have control of the commodity price to the ultimate consumer, regardless of the number of middlemen it passes through Another way of looking at the same point is that

Another way of looking at the same point is time, our patent law to-day gives exclusiveness to the inventor in making, using and selling lus invention. It does not compel him to do any of these, therefore, why should he not have the right to sell his patented article. under any conditions he sees fit? One of these condi-tions being to maintain the re-sale price. The offect of this decision will not only be felt by the manufacturer, of this decision will not only for feet by the manufacturer, who, by the way, through differential discounts and other means at his command, can more or less control the re-sale price of his commodity, but will drive out of business the retail dealer, who cannot stand the price outting which large department stores and mall-order houses could practise in certain lines of goods for the purpose of creating in the minds of the buying public that all of their prices are proportionately low; in other words, using certain well-known lines as leaders and making their profit on lines of goods whose estab

shed selling price is not known.

As to the ultimate consumer, he now has the asthrough the vast amount of publicity gi to standard lines of commodities, that he can put these goods at the same price from a small dealer as from a mail-order house or large department store. Rather than make it prohibitive for the manufacturer who sells his goods through dealers controlling the re-sale price, the small retailer and consumer would be more greatly benefitted by the law compelling manu-facturers and retailers to establish and maintain the same re-sale prices throughout the United States, leaving to their discretion as to what this price should h If they make this price excessive, their goods will not sell; if they make this price too low, they cannot stay in business. This would insure the ultimate consumer being able to buy a standard article at a standard price at any point in the United States, and make it impossible for large corporations to drive the local com-petitors out of business through their ability to out prices in certain localities, while maintaining standard excessive prices in localities where no competition

This very use of price cutting has enabled some of our largest corporations to attain their growth and maintain their monopolistic hold on their commodity, which would have been impossible had they been compelled to maintain a standard price throughout the country. Their shility to change their prices as often as necessity requires should not be withdrawn, provided the price-change effects all localities at the

One point which is apparently lost sight of by our legislators in the present wave of reform to protect the ultimate consumer is the fact that the consumer must produce to be able to consume. Those that promust produce to be able to consume. Those that pro-duce more than they consume are making profit and progress; those that consume more than they produce are on the read to bankruptey. If our law-making bodies would exhibit the same materiat in promoting the production end of our peoples' welfare that they now show in the consumption end, a great many of our business ills of to-day would be remedied and the

bur and little consumers would have the wherewithal to meet the rising cost of hving conditions so prominent in our national life to-day. THE AMERICAN MULTIGRAPH COMPANY, id. Ohio, H. C. Osborn, President. Cleveland, Ohio.

# Some Novel Uses of Compressed Air

## How Compressed Air is Used for Sheep Shearing, Cutting Sugar Cane, and Shifting Automobile Gears

A lit is a harmless, elastic field, non-combustible, and is the most widely distributed of all substances. We simply compress it and hold it in a condition of confinement. We must merely provide a vessel strong enough to overcome its elasticity. With air, when once a vent occurs, the pressure falls very rapidly and the

strain is soon re-

Riveting with Compressed Air.
The hammer dill, used in riveting and and misceilmeons machine slop work, important upplica tions of compressed air. Economy in the use of air is a feat-are of this tool. Small machines use from 25 to 30 cubic feet of free air per minute, the birger 35 to 55 cube feet per minute, and air at a pressure of 80 or 90 pounds - sometimes 100 pounds is generily recommended.
It is expensive to

iny pipe and rivel up the Joints in the ordinary manner. the hot rivets into the pipe, must first be provided; and the rivets have to he pushed up from the inside through the holes, the workmen holding the rivets against the blows Imring all this operation, light rivers are becoming cold, and the difficulty and anwork during the whole task, make it expensive and the results interior to riveting with comressed uh

Compressed Air Rammera.

Compressed air runmers for heavy work in foundries are simple in construction and accompilsh an enormous amount of work. Pig. 2 shows a tool for runming up en sand cores and molds of large surface area and

The tool depicted is suspended by the loop L; but much smaller single cylinder rammers are often used. apable of being carried around by hand.

capable of being carried around by hand. In the present instance, the modd is placed beneath the tool, and air is admitted from the hove V by the valve G, which permits the air to pass alternately to the cylinders A and A'. As the platon C rises, the air is exhausted at D; and when the end of the stroke is ched, the trip I operates the valve G to cut off the air from A, and introduces it in A', causing the pi C' to descend and thus strike a blow with the rammer E, the air being exhausted at D'.

The workman stands in the mold and directs the lows by the handles 8. Oil is sprayed into the cylin-

ders by the olier I and the compressed air

By the use of these machines, one man can readily
do the work of from eight to twelve men. The rammers use air at a pressure of about eighty pounds square inch and strike from two hundred and fift; to three hundred blows per minute.

Shifting the gears of an automobile with compressed air.

The Air Hoist.

The application of air hoists to cranes, planers and, in fact, to all conditions in which a holst may be useful, is now made in an almost endless variety of ways to meet the requirements of machine shop and foundry practice. The hoist is hooked to a tackle for adjusting

practice. The mine is noticed to a further to a distance in the height and the work is quickly done.

In Mag. 6 the valve lever 17, which is usually provided with a chain, is used to operate the three-way valve; 32 to admit, the sile from the pipe 14 to the cylvalves to distinct the six the piston 27. This raises the piston and the loss attacked to the hook 29. When it is marred to fewer the weight, the valve 56 is turned to open the 'core 12 to the unhant and admit airthrough the pine 25, which is connected to the valve casing, at the top of the piston The ports 35 are leak ports to prevent the formation of a vacuum, in case it

is desired to drop the piston by its own weight.

Few realize how cheap it is to operate an air holst. side from its convenience and speed in handling toads It has been estimated that compressed air at 90 pounds pressure costs about five cents per 1,000 cable feet of free air or 143 cable feet of capacity in the air lift; and with air pressure of 75 pounds per square inch a cylinder 5 inches in diameter, a weight of a haif a ton can be lifted or lowered four or five feet.

Combined Pneumatic Gear Shifter and Engine Starter. With the automobile starting crank securely incked away in the tool box along with other implements that seldom are used, it was quite logical to expect that the gear shifting lever too soon would be relegated to ce of comparative obscurity, and it is not the least bit surprising, therefore, that several devices, designed to lighten the burden of the driver by substituting mechanical for manual control of the transmission gears, have appeared of late.

Ever since the beginning of the automobile, comd air has proved a fertile field for the Inventorhistory has it that us long ago as 1800 an Englishman invented and patented a complete compressed nir auto-

mobile; but except for the pneumatic engine starter compressed air devices never have amounted to much up to the present time Now however, there has been developed a new pneumatic system which would seem to hold forth real promise, for the reason that in it complication has been reduced to the minimum. Not only does the system furnish compressed air for inflating tires and for starting the engine, but it also provides means for shifting the transmission gears and the effort required by the driver is no more than is required to advance the spark or to open the throttle. With this system, the operation of shifting gears has been reduced to a simple depression of the clutch

The principal unit in the system is the air compressor, of course—a tiny little four-cyl-inder machine with cylinders measuring two by two that serves also on occasions as the motor to start the gasoline engine. The compressor is geared to the crankshaft of the engine and is quite automatic in action the pressure in the reservoir drops below 200 pounds, a pneamatic valve

matically connects the compressor and re-flits the tank; when the pressure reaches 250 pounds the compressor is disconnected. The valves of the compressor are so arranged that when a lever on the dash is pulled, the unit becomes an aft motor. When run ning as a compressor, the gear ratio with the gasoline engine is 2 to 1, but when operating as a starter the ratio automatically is changed to 1 to 4.

In eliminating the ordinary hand genr shifting lever. the system merely substitutes for it a pision working cylinder, and a selector mechanism operated through a small steering column indicator; the operation of the device is best made plain by reference to Fig. 9. The shifter rods of the gearset are designated

(Concluded on page \$1)

# Fuel Production in the United States

## Present Consumption and Future Supply

By R. H. Byrd

THE United States has become habitually a half bli-lion ton coal country and at the same time a quarfor billion barrel oil country. In 1910 the production of coal for the first time exceeded the 500,000,000 ton mark, and in 1911, according to the official returns of that figure by only I per cent. The increase in the production of coal during the past decade has b

most speciacular. It was thought that la 1980 a high-water mark had certainly been reached with a produc-tion of 200,084,027 short tons, yel the production of the past two years has been mearly double, or 231,412,351 and 220,-504.281 tons greater, respectively. Judging from the most there is no good reason to supin production will not continue; and it will certainly be a year of poor industrial progress where the ontput falls far below the half blilion ton mark Indeed a study of the mine figures for 1911 shows that but for the depre sion in the iron trade in that year, la which coai largely lightes, the coal production would have ord, well in advance of 500,000,000 lons. estimated production for 1912 is about 540,-

In 1911. Pennsylvania as usual led all States in coal production, with a total of 235,185,370 short tons, 144,721,303 tons being bituminous total of 285,185,370 and 90,464,067 tons be-ing anthracite. This is vast production for a single State It is almost as much as the combined production of all the other twentyseven cont-producing States, Pennsylvania has a greater produc-tion than any foreign country except Eng land, and the output of a number of her ladi-vidual counties is greater than that of some countries which are classed as important

The second greatest roducing State was West Virginia, which mined 59.831,580 tons, the third coal State was Illinois with an output

In 1911 of 53,679,118 tons; the fourth was Ohio with 30,759,986 tons; the 1fth was Alabama with 15,021,421 tons—indiana, Kentucky, and Colorado, each produced over 10,000,000 tons

Fully as spectacular as coal is the production of petroleum, which has now attained a highly important position as a fuel and a commodity, and in many locali ties is successfully competing with cont. The follow ing table shows the enormously rapid growth of the petroleum industry since 1900

63 620 520 | 1903 | 100.101.337 | 1903 | 110.701.337 | 1907 | 110.701.337 | 1919 | 209.557.248 1911 ..... 220,449,391

This output for 191f was 63 1/3 per cent of the

total production of the world, despite the fact that the

world's production surpassed all former records.

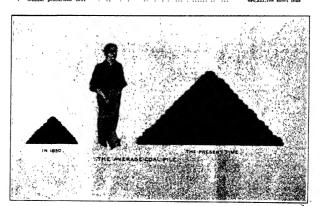

The value of the total production of coal in 1911 was \$625,910,118, of which \$174,952,415 is to be credited to the Pennsylvania anthracite production. price for bituminous coal was one cent lower in 1911 than in 1910-\$1.11 against \$1.12-and that of unthracite was three cents higher—\$1.93 against \$1.90-per reas valued at only \$53,070,515, the figures tically reversed. The average prize of the side West. Virginia coal at the uniness was ton, while that of was valued at only \$53,670,515, the figure ante west virginia com in the state of this of the thin of the much infestor Illinois com! \$1.11 a ton. Some West Virginia con! is shape (thicago. The reason for this is that West Virginia and in a manufacturing State, but that Illinois is or the most im

of her great coal resources, industries on th ir part the producers to get much higher prices than those which the West for their far superior grades of cost which they must ship hundreds and even thousands of miles from the mines. Comparisons beand Alabama are still more striking. In its important iron industry Alabama has a local outlet for most of its eight years the average price has ranged from \$1.19 to \$1.36 a tou. more than 30 per cent better than West Vir-ginia prices. In its high-grade cheaply mined, low-priced fuel, West Virginia offers advantages to the development of manufactures that should place it among the leading manufacturing States. As a matter of fact, it stands twenty-ninth.

With our coal and oil production increasing as it is by leaps and bounds, the question is often discussed: How about the ultimate supply? When will ex-haustion come? I'ndoubtedly the oil supply will go first. The petruleum reservo cannot be closely estimated, like coal deposits; but all estimates place the supply as running up into many billions of barrels so that complete exhaustion of even this fnel is a long way off; but when a few desul-tory facts regarding coal are considered, which may be men-tloned at random, it can

be seen that a genuine "coal pinch" for the American nation is a far distant contingency. For instance, bear ing in mind that the total amount of coal mined and wasted in mining up to the present time is approxi-mately sixteen hillion tons, consider the news item recently given out by the Geological Survey estimating the tonnage of the Bull Mountain coal field in Montana. The tennage of this single, little known, field is pigced at five billion tons. Again, a newly discovered field in New Mexico-the Black Mesa field—is conservatively New Mexico—the Black Mess field—is conservatively estimated, because of meager data, to constall a twelve billion tons. Again, whereis a few years since 60 per cent of the coal in a workable bed wes lost-in getting out the other 60 per cent, to dry the average is represent, and 60 per cent as saved. Another thing, for sometime, the new hundred billion time of Meridia suite install. the five hundred billion tons of Hamite and

Amount of coal mined and unmined in the United States.

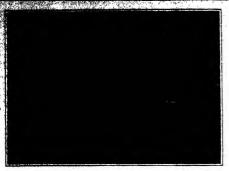

A comparative showing of increase in the consumption of coal (United States).

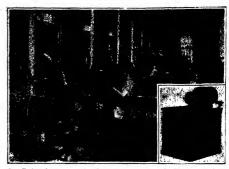

short ton. The total value of the oil output for 1911 was \$134.044.752, an increase of \$6.148.414 over 1910.

The analysis of the prices of both coal and oil in

the various fields affords some interesting study. West Virginia, for instance, which for the last three years has stood second in rank among the coal produc-ing States, the situation is unique in the low price which its excellent coal brings to the producer. The fromble is that the State has no well developed local markets and more than three quarters of her coal is shipped to distant ones, in other States. West Virginia in her remarkable coal deposits has a source of wealth in what it might create in the State were it used to develop home industries. Illinois affords a striking example of what West Virginis might accomplish. Hilnois is the third producing cost state and in former years has had seemed place. In 1911 size

builders and a few other enthusiasts of those days. metorcycles were far ahead of the time, and their worth unappreciated.

The only other steam motorcycle of which th authentic record was one made by S. H. Roper of Roxbury, Mass., in 1896. It consisted merely of a standard bicycle of the time, to which Roper attach steam engine of his own invention. It weigh pounds, but despite its weight and awkwardness, the er was able to secure considerable use out of it. and as a matter of course, to be the envy of his fol-low cyclists when head winds and hills were encoun-

taread.

In the meantisms, the gasoline motor was making considerable strides toward its present high state of development, and in the year previous to the appearance of Roper's mechine, 1805, the first public gathlition of mactorceptes in America was held in Madiona Square Garden, New York city. Easily the most senantional machine at the show was that of the Motor Cycle Company of Cleveland, Ohio, the leading spirit of which was E. J. Pennington. Pennington was a foremer, who saw millions in motorcycles, and had little difficulty in corresponding to the control of the control of the control of the correct his belief to the necessarian many others to accept his belief to the persuading many others to accept his belief to the extent of investing in his schemes.

His machine had been put on the road in 1894, and

uch notice was given it in the press, on account of a alleged wonderful capabilities. There was no ban its alleged wonderful capabilities. There was no bean on be introduction of gracinies in the Gardeen in those days, and the Pwanington machines actually were demoustrated in the basement of the famous amphibeater. Two types were exhibited, a motorycle and a motor tandem. Many people took advantage of the opportunity to ride in the front seat of the tandem, and with its four-inch pneumatic tired wheels, it certainly

a gas motor, it was not of the type used to-day, and as a matter of fact, little ever was known of its mechanism, or of the ignition or carbureting apparatus. was attached to an elongation of the right reas stay, and operated on the iocomotive principle with an exposed platon rod. It was claimed that kerosene was used, and that one gallou was sufficient to propel was used, and that the gainor was sundent to proper the machine 200 miles. One of Penington's marked abilities was his reckless handling of facts, and he claimed everything under the sun for his machines. Many people awallowed his claims without a whimper.

mington claimed to control a patent that covered any fluid engine or wheeled vehicle The assertion was made that the engine on this machine could run on any oil, but that kerosene was used because of its greater explosive properties. The failact of this claim is obvious, and the prevarication letar was exposed, with the discovery that gasoline and not kerosene was employed. The frame tube was used to convey the fluid from the reservoir to the motor, which was controlled by pressure of a push button located in the handlebar.

ington's project, staggering in imme put forward at a time when bicycles were on the top wave of popularity, and automobiles were just begin-ning to excite mild curiosity. However, there was no real interest in motorcycles or automobiles at that time, and Pennington's schemes were considered visionary. The motors were prone to overheat on the slightest prevocation, and they proved failures, but served to interest persons who later were directly responsible

dustry.

Seen after the show, Pennington suddenly found urgant business Pequiring his presence abroad, and be left behind many creditors. He later returned, when temposed that his bubble had been forgotten, to engage in sciences new. White American inventors were gage in sciences new. struggling with the motorcycle, it also was receiving persistent attention in several European quarters. Sevpersonnent attention in several nurspent quarrent Several increase affairs were ovired in 1894 and 1895, but the title turned so sixtengly to tricycles that temporarily the two-whosist was lost sight of.

Prominent assising the foreign motorcycles brought out; its the late, planties were the Volta, a French statute. The Computer of the Volta is the contract of the Volta in the Computer of the Volta in the Computer of the Volta in the Computer of the Volta in the Volta

out its the bits, making see the Young motorcycles bringing out its the bits, making sees the Young from the stanger; the Durens, another stam type from the land of Napolesu, but whose designer differed radically from Young in the 184 of hower application; and the passible model of Matrice Worner, which came on the gasuings moose, sanction weren, when came on the scope white we were burning powder with Spain in the West Indice in 1988. The Werner was considered a very practical machine for its time, and a number were built, which performed creditably. The motor was staged in front of the handlebars and transmitted power to the front wheel by belt

To all practical intents and purp of the American motorcycle industry dates from the year 1900, when the first American machine that deserves to be called a motorcycle was produced

The ground once broken, others followed the lead of the pioneer manufacturer, and in a short time a flock of designers scattered about the country amounced their models. Notable among these was Emil Hafel-finger of Hoboken, N. J., who brought out a particularly attractive design that remained standard for several years after, although his machine never was a in the industry.

While there are approximately fifty different brands of motorcycles built in America to-day, built of this number are produced in insignificant quantities ther are produced in magnificant quantities representative makers number about fifteen, thanically the motorcycle of 1913 is a very modern dole, taking the motor car as a standard. The repvehicle, taking the motor car us a standard. entative 1913 motorcycle has twin cylinders, this being the predominant type in the industry. horse-power is standard in power rating, and two speeds are conceded far superior to the single speed

Magneto ignition also is stundard, and chulu deivo again has gained the ascendancy, after a temporary ecipse in favor of the belt. To day the chain predomcupier in involve the sent result from the chain predominates, and there is a tendency to inclose it from dirt. Two types of engine starters have appeared, but the automatic ratchet type operated in foot pressure has proven most popular. The groatest advance of the ent season's models is in increased comfort. is obtained by the use of cradle spring frames and forks, using leaf springs as in automobiles, inclined footboards, providing a natural leg position us in a car, and abolishing the futigue of crumped limbs longer wheelbase and larger tires | Iguition is by waterproof magneto, and lubrication by mechanical Tail pipes and large expansion chambers deade effectually, double brakes assure absolute control, and large tanks afford a wide range of travel on one filling. Although the motorcycle of to-day is considerably cheaper than it was a few years ago, it is the best "buy" the industry ever has offered, and the fact that all prominent makers are swamped with orders indicates that the trade is enjoying the best season in its bistory, with still better prospects in sight for next year. The motorcycle has established itself in the commercial world permanently, and there its greatest future lies.

#### The New First Assistant Commissioner of Patenta

ROBERT T. FRAZIER of Nashville, Tennessee, the commission of Pirat Assistant Commissioner of Patents He is fifty years old, a native of Tennessee, was appointed to the Fulled States Naval Academy and was graduated from that institution in 1883, but was mustered out after a two years cruise with a number of classmates because there were no places in the service for them at that time

He entered the Patcut Office us fourth assistant examiner in September, 1887, and served in the various grades until his resignation in April, 1893, at which time he was a first assistant and about to be promoted to principal examiner. Leaving the Patent Office, he became a member of the firm of Howson & Howson on July 1st, 1901. in April, 1900, he became a member of the firm of Smith & Frazier, which was dissolved in July, 1910. In September, 1910. Mr Frazier re-entered the Patent Office as a fourth assistant examiner, since which time he has passed through the intermediate s and was promoted November, 1912, to the position of first assistant examiner. Like his chief, Mr. Ewing, Mr. Frazier brings to his new position a long experience, including practice within no well as before the Patent Office and in the courts

#### More Permanent Creosoting

THE old problem of retaining the creosofe in treated THE old proper of retaining the timbers seems to be solved in the new plan of applying the creosote with paraffin or stearle acid heated to the melting point. Of course the wood must be hot also. The mixture or solution of liquids penetrates to the heart of the timber, and on cooling the paraffin or stearic acid solidifies, holding the creosote perma-

#### Trucking Inside the Factory

THE cost of transporting material and partly fluished parts from one point to another within a factory is apt to n much higher figure than would imagine particularly where the transportation does not take place over any great distance and it does not pay to employ any special trucking method. In such cases the work has to be done with hand trucks, but even with the hand trucks improvements are possible which will result in conshierable saving. In the accompanying illustration we show a three-wheeled transveyor, the forward wheel of which is swiveled to allow the wheel of which is awiveled to allow the making of abort turns, while the super-structure is so arranged that it may be elevated or depressed with relation to the main frame of the truck. To make possible the transportation of "toto" boxes or platforms, it is merely necessary to provide them with shoes or skids of sufficient height to permit of introducing the transveyor under them. Then the simple action of pailing the handle or the tongue of the transveyor forward from the perpendicular to the horizontal postthe perpendicular to the horizontal post-tion will elevate the box with its load, when it may be wheeled to my other part of the factory. To lower the load it is only necessary to step on a pedal while holding the houlde in a horizontal post-tion, and then let down the platform by raising the haudie until it is perpendicuiar, after which the transveyor may be withdrawn. The elevating mechanism is withdrawn. The elevating mechanism is declarated to multiply the leverage sixteen to twenty times, so that very leavy leads may be elevated. After the loud is elevated the weight serves to lock the mechanism in raised position through the action of togate or knuckle joints. saving the handle free for drawing and steering the truck.

## Towing a Locomotive With an Automobile

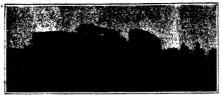

THE average automobillet, who does to the car, would perhaps have a better notion of this life had been a witness of a rather unusual test in Colifornia. A 40 horse-power touring machine weighting 4,000 pounds, was attached, by means of a strong cable, to a 110-tou locomotive. The cable ran from the axis of the car to the cowentcher of the locomotive. The start was made from a dend sandstill. For some time the motor car ground, and vibrated to no swall. The wheels refused to find a purchase and slipped around and around Planilly, half a dozen near were put into the car to do duty as hatlast. This additional weight had the desired effect. With slow reluctance the wheels of the monater in tow long aut to revolve, and the automobile had achieved the seemingly impossible task of drawing so

No injury to the car resulted from this great and unusual strain, and for some distance over the rails the mass of iron obediently tagged after its puny pilot. The demonstration was made by an

The demonstration was made by an automobile agent to show what a really powerful machine the motor car of today is.

#### Automobile That Will Run Suhmerged

WE have seen automobiles running when partly submerged, but it is decidedly unusual to find one that will work when practically overything is submerged except the driver's seat. This is now done in a new French automobile that is intended mathly for use in the colonies, where the car is likely to be required to cross rivers. It will be quite valuable for making trips in these reduces, where the rund is barred to the ordinary automobile by streams which of course have no bridges. The exhaust from the motor is taken off by a pipe which projects well out of water to the rear of the driver's seat. Air for the carbureter is fed through a pipe directly his front of the driver. The only light to the immersion deliver. The only light to the immersion

#### Peculiarities in the Growth of Trees

THE forester descode very largely on the annual rings of growth not only to determine the age of trees, but also to ossiculate the growth and yield of individuals and forests. Sometimes they serve a different purpose. A few years ago, in a lawsuit involving a forfeit of \$25,000 as unrely against the cutting of timber on alleged Tennessee State land, sections of trees trunks taken near the ground were admitted as evidence in locating an old stream bed which marked the boundary of the uricinal grant. This was made possible through the fact that the timber on the newer land was younger than that our the original banks of the stream and was also even-aged instead of all ages, thus showing that the change in the bed of the stream had been made rather suddenly and comparatively recently.

The occurrence of a severe fire, an insect infestation, an unseasonable frost, or periods of abundant rain or of drought may be read from the effects produced upon the structure of the wood from year to year. If a fire is severe enough to destroy portions of the cambium or growing layer of a tree the wound will event ually grow over from the edges. Even if entirely effaced from the outside it will appear upon cutting open the tree, and if the number of rings is counted from the very edge of the would to the bark the time of the fire can be determined with accuracy. The section shown in the iliustration is of a western reliow pine repeatre-scarred, but uble in each case to survive the injury.

The tendency of a tree to cover up an object attacked to it is commonly observed in the growing over of naths and wires. In the accompanying photograph is shown a pine cone naturally buried in the heart of the tree on which it grew. The cones of lodgepole pine are small and usually persist on the tree for many years without opening. In this case a cone remained so long that it was caught by the growing wood and completely enveloped.

#### European Dress in China

A CORDING to the American consultant Swarow, shortly after the revisition of 1911-12 there was a merical condition of 1911-12 there was a merical conditions of 1911-12 there was a merical condition of Chinese to adopt Darropean dress. Although the bulk of the people contil not afford to follow this feathon; there was for a time great demand for all more afford for a time great demand for all more worse, a reaction has set in, and it is said that of those win a dopping foreign stress last year perhaps on per centificative more back to native vicinities, 1981s, grays declining in typice about it great-majo, the lately rhose lately respectively.

#### a Ewing, Jr., the New Commissioner of Patents

A FTER an efficient administration of aix years Edward B. Moore retires Patent Office and makes place for Mr. Thomas Ewing, Jr.

The patent bar as well as inventors in general have reason to be pleased with Mr. Ewing's appointment; for like his predecesses, Moore, Allen, and Duell, he served for a time on the Patent Office staff. He is therefore thoroughly familiar with the ways of the Office. On October 22nd, 1888, he cutered the Patent Office as an assistant examiner after having passed the usual Civil Service examina-tion. He resigned on October 9th, 1890, having meanwhile been promoted

After leaving the Putent Office Mr. Ewing engaged in the practice of law in New York as a member of the firm of Ewing & Ewing. As might be expected, he has made a spec thus supplementing his fundamental Patent Office experience with actual active practice, both in soliciting and in con-tested work before the Patent Office and the courts. Mr. Ewing is therefore an incumbent who knows from experience both sides of Patent Office procedure.

Although a specialist in patent law, Mr. Ewing is also a business man; for he is president of the Current Literature Publishing Company. He has always taken an active interest in municipal affairs and economic conditions and was Democratic candidate for mayor of Youkers in 1897

It will interest manufacturers and inbefore the Cougressional Committee on Patents last year and strongly disapproved of the Oldfield Bill on that occa-

# A Controlled-key Adding and Calculating Machine

MODEL of an adding and calculating A machine just put upon the market contains several radical improvements which are said to be revolutionary in their effect on correctness of operation. effect on correctness of operation. The object of these improvements is to elim-inate to the last possible degree the hu-man element of error and thus guard against the mistakes of mis-operations due to the inexperience of beginners or the carelessuess of experienced operators. This controlled-key machine compels curintroduced to accomplish this astonishing result are: Interference guards at the sides of key-tops to prevent accidental on of a key adjacent to the one being operated; automatic locking of all other columns when any key is not given its full down stroke; an automatic block against starting any key down again until the mistake is corrected by completing the ne up-stroke is completed.

The significance of the first of these

automatic features is quite apparent. It is obvious that in a duplex machine, here two or more keys in different cola key standing next to the one in-tended to be touched may be accidentally depressed far enough to cause the unin-tentional adding of a number lu another degreesed far enough to cause the unin-tentional adding of a number in another column. This cannot happen in the new machine, because the key is made in two parts, so as to prevent its depression ex-

ept when struck squarely on top.
The second and third automatic added afaguards inche the machine practically satignardi inshe the machine practically proof against he faults of the operator. In order, to perform their proper function and correctly and their respective numeric states, the large must of course, be stren-tically full assembled travel or hoth the dequivered and return afrees. Others

touch is quickly acquired and soon be comes a fixed habit with the experienced operator, who is able to work at high out the aid of the controlled-key. The beginner, however, tempted by the rapid action of the machine, may try to go too antitude of the maximum, may try to go too fast at the start and by a slurred or par-tial key stroke, make it add a wrong amount. With the controlled-key feature such errors, whether due to carelessness or inexperience, are impossible. If a key is not given its full downward stroke, the keys in all the other columns are immedi-

ience to those sheent from their office or homes when others call them by phone e experiments were made in co with a number of subscribers of a Paris exchange whose telephone instruments were fitted with a special magneto. On turning a handle of this magneto a lamp would be automatically lighted at the desk of a special employee, who on receiving such signal outs off the connection with the subscriber's number and receives the salls for such number and notes down such communications as persons calling up such subscriber in his absence desire to give him. On the subscriber's return to the actely locked and the numeral wheel in the column where the error is made shows office another turn of the magneto handle

#### What Seems a Bad Practice

THE writer a short while ago, waiting for the elevator in the Patent Office building at Washington, overheard a conversation between two young practition apparently, but unknown to him, which indicated what seems to be a very improper practice. One said to the other: "He has number of applications in the Office and a number of applications in the Office and I don't know what they cover, but I think! I will slip in an application and find out." His purpose was evidently to file an application for patent for the purpose an approaction for patent for the purpose of ascertaining the subject-matter of some application or applications which had been filed by an another applicant in good faith. In thinking how this could be done ratts. In Emning how this could be done without actual perjury it cocurs to the mind that one might pursuase a device on "the market upon which application for patent had been filed and make some addition to it and file an application to it and file an application to patent outside the property of the

addition. In some, if not many, of the divisions of the Patent Office claims would be suggested, for purposes of interference with a previous application for the original invention and the second applicant could insert such claims if he desired an interwith a previous application for the original invention and the second cant could insert such claims if he estred an interference even without the formality of a supplemental cath. Or if he did not desire an interference, as he would not in the case above supposed, he would have obtained information from the Patent Office that an application for patent vas pending and contained claims, the uggested ones, which were deemed by the Patent Office to be patentable. The reprehensible practice above outlined should be avoided or blocked either by a stricter observance of rules in force, or by the institution of other rules which would effectually prevent the practice.

#### Home-made Lawn Rollers

MUCH ingenuity and considerable invention is displayed in the production of lawn rollers for domestic use. These are sometimes made of cement and frequently with the aid of terra cotta or metal pipe of untable length open at both ends and in which the cement is poured, form-ing a solid roller. Recently the writer ing a solid roller. saw a home-made roller in which the trunnions for the handle projected beyond the cement and these trunnions were at the coment and had its central portion flattened and perforated by bolt holes through which olts passed to secure a number of short engths of scantling which were used as folling blocks to reduce the amount of soment and thus lessen the weight of the roller. When terra cotta pipe is used, it can, when cracked, he entirely removed from the roller leaving the coment roller An ordinary lawn mower handl with arms of wrought iron which can be made by any blacksmith, supplies a suit-able handle for the roller and the entire ost is said to be very much less than the ordinary commercial roller.

#### Some Early Patent Office History

DOCTOR THORNTON, the first Superntendent of the Patent Office and who was appointed in 1803 by Jefferson to issue patents, continued in such office until 1827, a poriod of 24 years, his ad-ministration of the Patent Office being, it is believed, much longer than that of any of his successors. William Elliott, one of his associates who left the Patent Office communications received during his an-name and the transmitted to him. It is in May, 1829, in writing a letter dated claimed that the system is technically a January 16th, 1830, to John D. Craig, success and the question of extending it to all subscribers is being considered.

Office, said of Dr. Thornton, "he con-Office, said of Dr. Thornton, "he coneised freely much discretionary po exercised freely much discretionary power in the issuing of patents; for he held it as a maxim, and I believe a very good one, that the patent law was made solely for the 'encouragement of authors and inventors' and not to collect revenue." It is refreshing to find that such a spirit was entertained so early in the history of the United States Patent Office.

> Another Magazine Tobacco Pine .-- A patent, No. 1,058,232, for a tobacco pipe, the invention of Selim W. Gunn of Feeding Hills, Mass., shows in a tobacco pipe a ster which has the usual smoke passage which communicates with the bowl midway between the top and bottom and a magazine is arranged under the stem and communi-cates with the bottom of the bowl through an opening controlled by a shield, a plunger operating in the magazine to force the tobacon therefrom into the bottom of the

ARE, Dodge, Neb. This invention pertains to
improvements in telephone attachments, and
has particular reference to device of this character devised for the purpose of detecting the

interference with party lines due to unauthor-ised parties listening to a converantion. An object of the improvement is to provide a detector of the nature indicated which will be simpler and more effective than those berete-fore ordinarily proposed.

#### Of Interest to Farmers

Of Interest to Farmers.
BILE GRASS SEED HANTSTEEL—8, E
MCCORRE, McCornick Rive, Wincheste, Xy
An object of the invention is to provide a devire by means of which blue grass used may
seek for other receptacles at a maximum
rate and with very small loss of seed.
VINITILATOR FOR BROUDER HOUSER.—
C. W. BRICK, Crossvicks, N. J. This invention
reters particularly to a means for resultiating
brouder houses, and provides an improved form
of vacilitate and in connection theretin.

VENTILATOR FOR BROODFR HOUSES.

means for heating the air inducted by the vantilator; and to provide a safety valve ex teriority of the brooder house, whereby to pre-vent the delivery of 100 strong a current of air thereto.

MOTOR PLOW.—F. S. HOUBER, Cuba, Kan This invention relates especially so motor oper-ated plows. Among the objects of the inventor is to construct a mover ploy whose frame is of movel construction whosely the implement is adapted for better, gender and news consul-

1

eal service than is common in this ci-

machiney.

WHEAT CLEANER—J. J. RAMAUR, care of R. S. Coster, Lincolaton, N. C. This in vection has reference to machinery for winning or cleaning grain in mile or clerators and has particular reference of a machine of this type indicated for the thorough cleaning of wheat preparatory to the manufacture of the highest grades of flour in a flour mill.

Of General Interest.

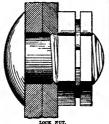

GASOIANE SEPARATOR.—C. S. Wasse,
Continenta Are. Believilis, N. J. In this
case the separation is gravitational, and the
scale the separation is gravitational.

MOLD FOR ELECTROTTPINO PROC.
SENER.—A J. TAILEY, care of B F Calevolt
in this instance the invention has reference
to moids for use in electrotyping processes using a cyanide bath and more particularly it is
directed to a new and improved mole whole
invented to a new and improved mole whole
invented to a new and improved mode whole
servation.

STRAP LOOP.—In Sanusa, G2I Broadway,
New York, N Y This invention relates to
metallie loope for various strays, including
bein, but has more particularly for its design
us stiggs sepondally of army rifles, where a
closed loop cannot be passed onto the siling
from an end theorof, owing to the other fittings of the sling.

#### Hardware and Tools.

LOCK NUT -1. D. ETTERMAN, 8518 Moni-gall Are, Kansas City, Mo. The invention per-tains to lock nuts to be need with the ordi-nary ants of boits in railway joints, and in other situations where nuts are subjected to vibration. It relates particularly to conceve

nnts. The inventor provides a nut having a concave side in which the threads will be from mutilation at the concave side and that readily engage a boil. Gripping means provide for engaring the opposed face of the ordinary nut with increased effectiveness.

#### Heating and Lighting

Heating and Lighting.

GAS FURNACK.—E II. Thorran, ear of Driver's Union Nock Yards, Caimboa, Ohio Tree investor Nock Yards, Caimboa, Chio The investor relates to a form of gas furnace to the control of the properties of the control of the properties of the proportion to the fire some Heated art is rapidly and economically carried away from the farance through the heat-carrying pipes, in this furnace the fame is in direct constant.

LRNS SUPPORT.—W. T. FRIEN, C. E. JONES, and F. T. Friend, care of F. T. Fried, C. E. JONES, and F. T. Friend, care of F. T. Friedd, P. O. Box 1246, Saaford, Fis. The purpose-term is to provide an improved less support for use on ismips and arranaced to permit of residitive to the source of tight with a view to concentrate and direct the rays of light to a desired point or object for rending OIL BURNER.—B. Grating Stockel Flield During Rein, scale, Nos. 1993, 189 and 1,093, 189. Owner L. Hedges and Arbur M. Franch C. Gelst, Mr., provide for cover which is extended to incente hashed field all as for books and masts for suppor-tion severe and adjusting them in un-ternative and adjusting them in un-

wen measure, over the field to be protected.

A field insisting There Pot.—William A. arthur in the property of the connection, with a water sweer job in connection, with a water meghade coveraged above it and having medicals leading down to the pot with a sire by which the flow of the water may registered.

A Thomas A. Balson Reproducer.— homas A. Edison, assignor to Thomas A. dison, inexposated, has secured patent is a reproducer for talking machines in talch is provided a disphragm composed a municum of machines. the he provided a dispirage composed a number of superposed sheets of Japaspaper inited unto a unitary structure, a saper inited unto a unitary structure, seastly yielding member is located contrically with one of the faces of the destroomy with one of the faces of the disphragin and extends into proximity to the periphery thereof, and the said elastic member decreases in thickness from the senser to the periphery. The patent is No. 1.068.021

A Return Savelege Long Retained.—As indicating the persistence of advertising and the tensoity with which some people retain a paper or an address, it is noted that the Washington office of Munn & Co. halfy received a return addressed en-age, with the printed address of such se at the somer of 7th and F Streets, while the office was moved from such loca-tion on the last day of the year 1865 more

A Confidential Telephone Transmitter.—
Maximilian Well of New York city, in patent, No. 1,088,120, 360ws a telephone transmitter in which there is combined with the disphragm a speaking ohamber which is adapted to receive and prevent the escape of a sound wave of speech, such chamber being formed with vacuum jacketed walls and with a mouth piece conor approximately to the mouth of the

Computing Scale with Automatic Cuteff.—A San Francisco inventor, sonn s. Duffle, has secured a patent, No. 1,057,811, for a simputing scale. It has a hopper normally closed and a latch adapted to hold the gate open with an electro which, when energized, will open the latch. whish, when energized, will open the latch. The computation chart of the scale has a hand which can be placed at the desired opint on the chart. Another hand, open-sted by the weighing apparatus with ele-urical whostly, energized the magnest when the two hands are brought together to close the color.

the sizemit States to at Enventer.....Robert Fulton has a estone in the hall of Parie, Statuary Hall of the States to the state of the States to the Hall of the States Challed States Chapted a Wandlagton. Inventees who viet the building will doublest be interested in this imposing work, which represents Fulton seated with a model of a steambeaute in this hand. The chapte was encouled in 1894 by Howard Robbart and whe purchased by the State of Pennsylvania at a coint of \$7.000. It was allowed by the States in Statespare.

shifting eministed from this bureau. The bureau would regret sky ortholom that weight injure the business of any firm mak-ring efficient machine, but it must be noted that the maker of an efficient machine would undoubtedly selse the advantage coffeed by publicity by proving by demo-stration that his device is effective. No sersion that his device is execute. No prolonged test is necessary in such a case, and the proof or disproof can be seen by a glance at the peeled potato. No criticism can thus injure an efficient machine."

Wanted: Machinery for Leves Building Wasted: Machinery for Leves Bulking.— —16 is pointed out in the Baginsering News that "The leves along the lower Mis-stastpp River from Caire to the Guit con-tain nearly 250,000,000 emble yards of earth, a greater volume than the total excevation on the construction of the Panama Canal. Practically all this work on the Missteippi leves has been done by either hand-cower or hones-power. The on the Mississippi leves has been done by either hand-power or hone-power. The negro pushing a wheelbarrow and a team of mules pulling a drag scraper proposent the motive power and tools by which almost all this enormous volume of earth has been moved. At the present time the probability seems strong that a great addition will be made to the Mississippi leves and the contract of the description of the contract during the next four or five years. The floods of 1912 and 1913, following in such oloss succession, have aroused the people of the valley to the realization that the present leves system, while it has for a long term of years, from 1897 to 1912, kept practically all the flood waters off the lands of the data, is not secure enough and high enough to guard the years of exceptional flood. It is probable, therefore, that dur-ling the next five years many millions of outlie yards of earth will be added to the Missistippi leves line, and there seems to be an opportunity here for the manufac-turers who have developed new forms of excavating apparatus and earth-handling mackinery and for the contractors familiar with the use of such mackines to prove the value of those devices."

The Unique Organization of the Patent Office.—The Patent Office, as at present constituted, presents a condition of affairs believed to be unrivaled in any civil de-partment of the Government. We have partment of the Government. We have here one of the most important bureaus ever instituted by the Government. In it the head, his two assistants, the chief clerk all the law clerks, the board of examiners the had, his two assistants, the chief clerk, all the law clerk, the board of examineration-hised and the chief of the cleanification division, the entire ranking official force of the office, are men who entered the office at the lowest grade of the examining corps and have passed through the intermodiate grades to their present positions. There is not recalled a previous administration of the Patent Office in which the Commissioner attered through the several grade is not proceed through the several grade is continuous service until he had reached the position of Commissioner. This is true of his two assistants as well and of the other officials appended above. No other efficials appended above. No other efficials appended above. No other officials appended and the control of the control 1907 when he was appoint he President Rossevelt.

A Ges-engine Starter.—Russel J. Mac-Larin of Grand Rapids, Mish, assignor to N, Jay MacLaren of sums place, has a pei-cus, No. 1,088,947, for an impine startes in which a test containing fixed gas under pressure in countries of the containing the countries. whiteness (D. C., union which a seak containing fixed gas under pressure is contained with the Intake manifest and pressure is to the manifeld and mease six and pressure in the Intake manifest and pressure in the Intake manifest and pressure in the Intake manifest and Intake in I

## CARBON DEPOSIT—How to reduce it

Considerable nonsense is current about carbon deposit.

Any product that will burn must be largely carbonaceous.

Lubricating oil will burn and is therefore plainly carbonaceous. Non-carbon oils cannot exist.

But the amount of carbon deposited depends on the carburetion and gasoline combustion, and on the character of the gasoline, as well as on the lubricating oil itself and its fitness for the car.

The presence or absence of carbon deposit in no way determines the lubricating efficiency of the oil.

Under identical conditions. however, some lubricating oils will give much more carbon deposit than others. This is due, in part, to three conditions:

(1) The crude oil from which the lubricant was manufactured may have been unsuited to gas engine pur-

(2) The oil may have been im-properly manufactured or filtered.

(3) Its "body" may permit it to work too freely past the piston rings into the combustion chambers.

To reduce carbon deposit, it is absolutely necessary to use an oil whose "body" is suited to your piston clearance.

In our chart of recommendations printed in part on the right) we becify oil of a "body" suited to the (printed piston clearance and other lubricating conditions in each motor.

The oils themselves are scientifically manufactured from the crude bases best suited to motor car lubrication.

They are thoroughly filtered to remove free carbon and other impuri-

If you are particular about your fuel, and your carburetion and igni-tion, the grade of Gargoyle Mobiloil specified for your car will put an end specified for your car will put an end to unnecessary carbon troubles.

Motorists often select their lubricating oil with an indifference that is lit-tle short of reckless. The penalty is paid in a multiplicity of motor

If you use oil of less-correct "body," or of lower lubricating quality than that specified for your car in our chart, unnecessary friction must result. Serious damage will ultimately follow.

In buying Gargoyle Mobiloil from dealers it is safest to purchase a full barrel, half-barrel or a sealed fivegallon, or one gallon can.

Make certain that the name and our red Gargoyle appear on the container.

A booklet, containing our complete subtricating chart and points on lubricating chart and points on lubricating will be mailed on request.

## Won't Freeze Onto the Pipe or At Nut or Seat

Because they are Sherardized after threading, a new process which gives surface and threads a "skin" of zine alloy, on the same principle that case hardening alloys the surface of a

Galvanizing a fitting does not protect threads because threads must be cut after galvanizing is done,

Ends are tapered at the threads to the Briggs standard taper of pipe.

This permits screwing up the Mark Union the full depth of threats. When you screw ordinary unions having a straight thread onto taper-thread pipe, only a few threads are in meth, leaving a nasty pocker at each end to fill with dirt and to corrode and freeze into a solid mass of rust.

#### Mark Unions Are Cold Drawn From High Grade Box-Annealed Deep Drawing Open Hearth Strip Steel

This is the first time a rolled steel product has been used in making a pipe union. All other unions are either gray iron, malleable iron or brass castings

You know the unavoidable defects of any cast article-blow-holes, sand-holes, unevenness, brittleness, brittleness, evenness, brittleness, etc. All these defects are absolutely avoided in Mark Cold Drawn Steel Unions,

Only the very highest grade of flawless, tough, homogeneous steel will stand the series of cold drawing and upsetting processes through which the Mark Unions must go. Every draw is a severe inspection test, and every draw also toughens the metal.

The last operation on the male end forces the cold metal into the tool steel die with such a tremendous pressure that it densifies the seat, rendering it almost glass hard.

When the union is screwed onto the pipe this densified steel seat is pressed into a soft brass seat ring, making an absolutely steam-tight joint.

Both steel seat and brass seat ring are formed with such absolute ac-curacy in hard steel dies that no machining is necessary. This means that all Mark Unions of any size are absolutely interchangeable

These are only a few of the many important points about Mark Unions.

When sending for our literature give us the name and address of the dealer from whom you buy most of your pipe fittings

#### Trade-mark Notes

Trade-mark for Wrapped Tooth Picks,— Assistant Commissioner Tennant in the case of Lowenstein v. Hers has affirmed the on of the Examiner of Interferences canceling trade-mark registration No. 73,-562, to Alexander Hers, the Assistant Commissioner holding that the trade-mark, which consists of two short parallel lines ade of transverse grillings or corrugations connected by a relatively long line of such corrugations, is but a feature of the pack-age incident to an old and well-known method of sealing the same and so not espable of adoption as a trade-mark.

Color as a Trade-mark Feature.—In the case of exparts DeWitt Wire Cloth Company, the Commissioner of Patents in affirming the decision of the Examiner of affirming the decision of the Examiner of Trade-marks to the effect that a trade-mark for wire rope described as a fiber once in the wire rope, which core is solored pur-ple, is not registrable, where it appears that it was old to use cores for usuch ropes made of asbestos, of fiber scaled in tar and of tarrod hemp or Manila rope, refers to cer-tain patents, granted before the applicants ed date of use, which show wire rope claimed date of use, which show wire ropes having fiber cores, and said, "These ropes have a color which, it is true, is different from that said to be used by applicant; but, as pointed out, the registration of this mark would give applicant a prima face right to stop any other person from using a rope having a colored fiber core and for this reason the mark is believed to have been properly refused registration by the Ex-ammor of Trade-marks."

Trade-marks in Cuba and Paraguay.-Consul General James Linn Rodgers, of Havana, advises American manufacturers erchants to register their trade and merchants to register their trade-marks in Cuba as soon as possible. In Cuba priority of registration gives the ex-clusive right to use a trade-mark. The consequences of this law have been grievous consequences or this law have been grayous for more than one manufacturer. For ex-ample, the trade-mark of one of the oldest piano firms in the United States was regis-tered by a Cuban dealer and thereby became his exclusive property. Practically the only course left for the plane company is to purchase from this dealer the right to is to purchase from this dealer the right to use the mark in Cubs. It is obvious that there is nothing to prevent the registration of popular trade-marks merely for the purof making the manufacturer buy privilege of using his mark in Cubs. Re-peated efforts have been made to have this eature of the trade-mark law amend

but thus far without success. Similar conditions are reported by Con sul Cornelius Ferris, Jr., of Asuncion, wh writes that American manufacturers should realize the need of protecting their trade marks in Paraguay by registration. Regis tration alone gives the right to the exclu use of a mark in Paraguay. Formerly many American manufacturers thought the ossibilities of trade in that country did not warrant the registration of their marks. Now some of these manufacturers have made the unpleasant discovery that when made the unpleasant discovery that when they want to sell their goods there they can not do so without coming to terms with some persons who have already registered the marks of the American manufacturers in question. Since priority of registration is practically the only test as to the right use a trade-mark, promptuess is advis-

The Hump Trade-mark .-- The Court of Appeals of the District of Columbia, in The Hump Hair Fin Company v. The DeLong Hook and Eye Company, has reversed the decision of the Commissioner of Fatents surtaining the opposition by the DeLong Company to the registration by The Hump Hair Fin Company of the trade-mark presented, and including the words "the hump," and in so doing held that the fact that two articles are included in one of the cleases established by the Commissioner of Patents under the act of May 4th, 1900, does not of itself make these articles of the same descriptive properties; that hairpins and hooks and eyes are not goods of the same descriptive properties because one could not possibly be used for the purpose to which the other is applied so that then Appeals of the District of Columbia, in The

price of the control of the co

t.—In the case of United States ward L. Chott v. E. B. Moore maissioner of Patents, and A. G. Wills. Primary Examiner United States Pat-Office, the Supreme Court of the Tilem. Teinany Kenninas United States Patsial Cilles, the Sugression Court of the Distoks of Columbia in positioned to great a
write of mandamen to casses the issue of a
patent to Chott. The application for pateits, which relates to a dantal broadholder, was finally released by the primary
causiner and appeal was filed to the board
of anaminer-shoulded, who reversed the
prinary causiners' desides upon the
ground that the references olded were from
a mon-analogous art. The examiner thereupon made a further search and rejected
the claims upon other references and reaupon made a further search and rejected the claims upon other references and reacus, and his action re-opening the case for the purpose of introducing additional references was approved by the Commissioner. The Commissioner of Patents also took up The commissioner of Facents asso took up the case for personal consideration of the morits of the alleged invention claimed, concluded that the application set forth nothing upon which a patent could prop-erly be based, rejected the claims, refused a patent, and said that appeal from his de-cision to the Court of Appeals should be taken, if at all, within the time prescribed by the rules of that Court. It is contended by the rules of that Court. At is contended in behalf of the petitioner that the authori-ties cited by him at length render it clear that the primary examiner could do noth-ing in the application in question, after ed by the examiners-in-chief, ne application. Further, that but allow the appli the Commissioner has no authority to pass upon the validity and patentability of claims unless the question comes to him by regular course of appeal, and attention is

omined to the Suppreme Court decimen in zerol. Miller v. Raum, in which it was held "When a subordinate officer is over-ruled by bls superior officer having appoilate jurisdic-tion over bim, his duty to obey the deciden of such superior is a ministerial duty who he eas be compelled by mandamus to perform."

The case at this writing waits the decision of the Supreme Court of the District of

The point involved seems to be whether favorable decision of any of the tribunals of the Patent Office can be set saide. In a oited precedent there was a strong dissent-ing opinion, and the writ if issued may affect a practice which prevailed for some affect a practice which prevales for some time of reviewing cases favorably passed upon by principal examiners and which re-sulted in withdrawing numbers of applica-

Bakelite Patent Recognition.sult of negotiations between the General Bakelite Company and the Condensite Company of America, the suits brought by the former against the latter and its custom-ers for alleged infringement of the Bakelite patents have been withdrawn, and the patents have been withdrawn, and the Condensite Company, recognising the pioneer abaracter of Dr. L. H. Baskekand's work, has acknowledged the validity of the Bakelite patents in suit and some others, and will pay substantial royalties thereunder. The General Bakelite Company will continue the manufacture of Bakelite under its numerous patents, and the Con-densite Company will manufacture Condensite under the Aylsworth patents as well densite under the Ayaworth patents as was as the license just granted for such of Backeland patents as are broad enough to cover Condensite. This recognition of the force and validity of the principal Backeland patents by the only other manufacture land patents by the only other manufacture of condensation products is a confirmation of the Bakelite Company's claims for the broad scope and pioneer chanceter of these patents. There is much that is old in the sat of misting phenoids condensation products, but if the Heavisland was the first to make principles application of what therefore had been elikely inhoratory experience.

#### nce and Modern Merchandising-II How Price Maintenance Benefits the Public By Waldemar Kaempffert

FT HIS is the second of a series of short articles intended to set forth in a simple incus the consonic necessity of fising and maintaining the retail price of certaining of manufactured products. Merchandleing methods have changed in the last irrently years—changed chiefly because notion-olds and world-cide ceiling has been made possible by advertising. In this remarkable development of business, consonic made possible by advertising. In this remarkable development of business, consonic made possible by advertising. discoveries have been made which are not yet reliefly known. It is these criticis to set forth those discoveries so far as they affect price Formal.

Independent manufacturers insist that cents the very blades for which you have the more efficiently and widely their goods been accustomed to pay \$1. The saving are distributed, the greater is the benneit is considerable, and accordingly you buy to the public. If hardware is concentrally your blades at the chain store. the public. If hardware is concentratto the public. If hardware is concentrated either in storerooms or in a few large department stores, it is made difficult for the buyer to purchase. He must always rely on the nearest distributing point. If that distributing point happens to be a department store several bundred miles away, he is delayed, often needlessly, in statisfying his wants. Distribution is the art of reaching the consumer; not the art of making the consumer reach the manufacturer.

The modern merchant realises that the greater the number of retailers who handle his goods, the more accessible will his wares be to the public, and, therefo the simpler will be the problem of dis the sampler will be the problem of this ribution. But to secure the widest pos-silde distribution, the many retailers who exhibit his wares for sale must stand on an equal footing. In other words, they
must all leable to buy at the same wholeale price; they must all sell at the same retail price.

That end is attained by so adjusting the rhat end is attained by so adjusting the selling price of an article that it yields a fair profit to the manufacturer and his distributors, and yet induces the public to buy because it is low. The selling orle must be maintained, so that the Broadway shop deals with the public on the sam

terms as the general store of a village Rural communities should not be obliged to pay more for merchandise than people who dwell in cities, yet with open prices they are often compelled to do so A widely-advertised watch that sells for a dollar all over the United States cometes with a watch of about the sau ercial value, but which is not sold at a fixed price. While the dollar watch in question can be bought anywhere a one price, and the retailers who sell it al make the same profit when they buy it is the same quantities, the competing watch is said in the larger cities by the larger dealers at 98 cents and elsewhere at prices ranging from \$1 to \$1.25.

What happens when prices are cut an oods are sold at a distinct loss by a mail goods are sould at a distinct loss by a man order house or a chain store? Suppose that you need a dozen new blades for you safety razor. You have been accustomed to paying one dollar for them—a price which has been established because means a fair profit to the manufacturer and to the retailer. A chain store in your town advertises that it is selling for 6

S PRUCE gum is one of the minor for-ost products which is generally not taken into consideration by the forester in this country. In Enrope a strict ac-count is kept of such small incomes and an effort is made to develop the minor yield, together with the major produ The gathering of the spruce gum con tutes an odd phase of the north woods man's life and to him often represents a comfortable livelihood. Spruce gum is a product of red spruce of the northeasters States. Maine, New Hampshire, and Ver mont contribute largely toward the an-must yield. The sum costs out through abrasions in the bark, smally caused by borers and frequently by reachs or checks in the bark-due to the unequal thawing after excessive cold of the winter. The for plugging up the heles or cracks in the s through and often forms vari ous fantastic shapes upon the bark of the trees. At first it is soft whitish and

When next you have occasion to buy a dozen safety razer blades, you find that the corner druggist from whom you once bought no longer carries them in stock Why? He was unable to com the chain store. The chain store has long since consed to advertise the razor blade Still, you try to purchase a set there. At the cutlery counter you are told that the razor blades are no longer carried in tock. If you want a set you must write directly to the manufacturer for them.

While this is a hypethetical experience while this is a hyperhetical experience it is one that actually occurs frequently. Only the price of a very widely-advertised nriled is cut, one which is bought because of its acknowledged merit, one which is guaranteed by a reputable maker. If the retailer fluids the detailer of the price the demand for that article suddenly extinguished because a department store is offering it at less than cost, he is com-pelled to discontinue its sale. His stock is usually so small that he cannot sell other less well-known goods at so large a profit that he more than reimburses himprofit that he more than remnurses him-self for any loss that may be incurred by selling a widely advertised razor blade at less than cost. Thus, the clitzens of a small country town who were at one time able to luly a thousand different adver-tised wares -hats, shoes, hardware, and package food-stuffs-at exactly the sam price as the citizens of every other com munity in the country, are compe deal with a distant mail order house. And thus the way to a distributing trust is paved, a trust composed of department stores and mail order houses, who may dictate to manufacturers.

If the mail order houses, the depart-ment stores, and the chain stores were willing to sell well-known guaranteed articles at a loss, year in and year out, if manufacturers were willing to countenance this trade on their own good name it might be possible to advance an argu ment or two in favor of the practice. price cutting continues only for a short Its chief purpose is to attract trade, to give the impression that other articles, on which great profits are made are sold at an equally low rate. that purpose is attained the price-cutter drops the undersold article from his stock. Hence the public finds it very hard to buy the desired goods at any price.

commences to turn red, when it is fit to be gathered for market.

The gam picker frequently spec

time during the spring going about mark ing and scarring the trees, so as to mal sure of finding enough gum to pay for his labor when he calls around a yes his more when he cains around a yeer of two later This is done by elimbing a thrifty irre to above the old limbs and high in the soulight, and searring the south side of the trunk between the whorls of brunches with deep inclines shaped like the letter V. Making arti-ficial provision for the exudation of spruce gum in a systematic method has only recently come into practice. thrifty trees rarely have gus Healthy m on the It is found on trees that have been tunted from some injury, or are infested by insects, or otherwise diseased. Occasally one will find a tract where nearly all spruces yield gum.

It is said that the be pitchy, but after the intense cold of the day from 8 to 10 pends of craffic garden and fars where the because hard and changes though from 8 to 10 pends of craffs garden where it becomes hard and changes though from 3 to 5 pends constitutes as a darker hue. After the first year the fair day's work. By the time the garden is a darker hue.

## How Manufacturers Can Increase Their BUSINESS

Read Carefully, Every Week, the Classified Advertising Column

SCIENTIFIC AMERICAN Some week you will be likely to find an inquiry for something that you manufacture or deal in. A prompt reply may bring an order.

WATCH IT CAREFULLY

The VILTER MFG. CO.

cleaned it will shrink about one fifth in weight, which is worth from \$1 to \$1.50 a pound. The best grades of gum frequently bring \$2 a pound. Bangor, Maine, quently bring \$2 a pound. Bangor, Maine is the principal trading point for spruce gum. Many tons of it are shipped from here every year, and the bulk of it is sold in New England, where the gum chewers much prefer the spruce gum to that kind which is manufactured from parafin and

#### Novel Uses of Compressed Air (Concluded from page 9)

S, only one being shown, and opposite to them there are two idler rods, designated I, which are differentially geared to the shifter rods through the pinion G. The selector finger F, which is made integral with the piston rod PR the piston P and with the piston rod PR the piston P and the long pinion PL fits into slots in these shifter rods and idler rods when rotated through the smaller pinion meshing with the pinion PL; this smaller pinion is coned to the steering column indicator.

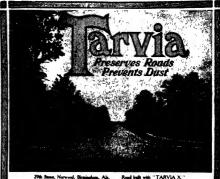

The air distributer is controlled by the clutch position. With the clutch engaged, the valve is closed; when the clutch is disengaged the valve is in the position shown admitting air behind the piston and forcing it back. In action, a neutral col-lar on the piston rod, on its backward movement, throws all the rods to the neu-tral position. Depression of the clutch pedal first closes one port and then opens communication with the other, forcing the piston forward, the selector finger drawing the rod selected by the steering col-umn indicator. The action of the device, therefore, is first to place the gears in the neutral position on the downward pres-sure of the clutch pedal and then to ensure or the clutch peak and then to en-gage the gear indicated by the steering column indicator on the upward move-ment of the clutch pedal. It is possible, however, to slip the clutch, without the necessity for changing the gears, a certain amount of leeway being provided for this

The particular advantage of any sys-tem of the kind, aside from the fact that it eliminates a certain amount of manual labor is that it permits the driver to have moor is that it permits the driver to have both hands on the steering wheel at all times. It also is possible to anticipate a gear shift. In ascending a hill, for in-stance, the steering column indicator is set for intermediate speed while the car is running on high gear and then the next time the clutch pedal is fully depressed. intermediate gear automatically gaged without further work on the part of the driver. To prevent reverse gear being engaged when the car is running forward, the reverse position is protected by a latch and to facilitate night driving the indicator is illuminated by a small

#### Fuel Production in the United States

underlie North Dakota (besides a vast tonnage in other States) until recently was considered to be worthless for any thing but the most local consumption. It is now known that all this coal ranks high as a gas-producer fuel, being more effi-cient in the gas-producer engine than the best Pocahontas coal under the ordinary steam bolier, and furthermore that it can be made into high-grade briquet fuel by simple pressure, without the use of the expensive "binder." Again, our present expensive "binder." Again, our present total estimate of thirty-two hundred bil-ilon tons of coal in the United States (exclusive of the great deposits of Alaska) clusive of the great deposits of Alaska) takes into consideration coal to the depth of only 3,000 feet. Coal lying beneath that depth is classified by the Geological Survey as "non-coal," however thick she Survey as "hon-coal," nowever thick sae seem or high-grade the quality. Yet Bel-gium is operating a mine but a few feet short of 4,000 feet in depth, and Germany estimates her coal reserve on the basis of a 5,000-feet depth

a bottom rest depth Finally, approaching the subject from the slant of the most economical use of the ton of coal after it is mined and de-livered to the power-plant or the factory; only a small proportion of the stored,

## The Modern Road Binder

LAIN macadam roads are adapt to slow horse-drawn traffic. Mod-traffic, with its high speed, dising es and destroys the ordinary macade nineral binder cannot resist the thru

Roads adequate for modern traffic must be bonded with something adhesive, duc-tile and resuting. Such a binder is Tarvia, a special prepared coal tar compound which retains its good qualities through all weathers and seasons and holds the stone

Tarvia is made in three grades:— Tarvia X" is a very dense material to

use as a binder in the large voids of new construction; "Tarva A" is of thinner constancy for surfacing operations; "Tar-va B" is used cold, can be applied from a sprinking cart and is sufficiently lamped to percolate into the pores of an old and well compacted road

"Tarya X" is required where new construction is called for. "Tarva A" and "Tarva B" are used in improving and protecting roads already in use

A tarviated road or pavement is practically dustless and mudiess and the maintenance cost is, in most cases, so reduced as to more than save the cost of Tarvia

# The Ten Greatest **Inventions of Our Time**

We hear much of the great inventions of the pastthe telegraph, the sewing machine, the telephone, the reaping machine, photography, Bessemer and open hearth steel, the steam engine and the phonograph. Yet the inventions of our own time are as epoch-making and as dramatic as these.

Perhaps because we have become accustomed to the use of the old machines and discoveries, perhaps because the achievements of latter-day inventors succeed one another so rapidly that we are not given much time to marvel at any one of them, we have not fully realized how stirring and wonderful are the products of modern ingenuity.

Only five years ago the man-carrying aeroplane made its first public flights; only the other day hundreds of passengers on a sinking ship were saved with the aid of wireless telegraphy. At least a dozen inventions as great have been perfected in our own time, and all of them have made a man's work count for more than it ever did before, and have made the world more livable than it ever was.

Why should we not tell the story of our own deeds? Why should we not review the industries created by men who are still living, men whose names will go down into history with those of Watt, Morse, McCormick and Howe?

That was the underlying idea of the November Magazine Number of the Scientific American. We knew that the "ten greatest inventions of our time" was a big subject when first we planned the number, but how big it was we never realized until we surveyed the field of modern invention.

Then we saw how astonishing was the progress made in our own day, how much mankind had benefited by the inventions of great modern intellects. We began to appraise inventions, to weigh one against the other, and to determine in our own minds which ten had contributed most to human progress and happiness, which were really great pioneer inventions, and which merely remarkable and valuable improvements on successful past conceptions. There were so many achievements to consider that it was hard to arrive at a definite conclusion.

The upshot of our own thinking has been to leave to our readers the decision

# What Are the Ten Greatest Inventions of Our Time, of applied science, but also in the prose and Why?

For the Three best articles on the subject, we offer in the order of merit, three cash prizes:

First Prize: \$150.00 for the best article Second Prize: \$100.00 for the second best article Third Prize: \$50.00 for the third best article

On another page of this issue are printed the rules that will govern the contest.

energy in the coal lump is utilized to-day the railroads use annually about 90,000, 600 tons, yet it is estimated that not more than 10 per cent of this energy is utilized to drive the engine winels; and this is far more than formerly. No one can doubt that during the next gen doubt that during the next generation there will be vastly more use and less waste in every phase of the industry ranging all the way from the mining, to the final application of the power. The present up-to-date plant, for instance burns its smoke and saves the power it wont to waste into the atmosphere, a fuel bill and a greater gain to the p in the absence of dirt. Directly and in-directly the smoke anisance is estimated at the country between \$250,000,000

#### Observations of the Companions of Sirius and Procyon

IN No 648 of the Astronomical Journa Prof. E. E. Barnard of Yerkes Observa tory publishes his results on his "observations of the companions of Sirins and Procyon." Because of the great bright of the principal star in each case which is particularly troub the air is not perfectly steady, conditions have seldom been good for observing for such oldects as the companious of Strius and especially the close companion of

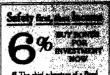

In the present observations of Sirius it has seldom been necessary to use the hexagonal disphragm (A N., 4845). with it Under good conditions the small star is a very bright and conspicuous ob ject. A little disturbance in the air, how ever makes it faint or invisible. The folwing ure the measures of the companio of Siring

82.34

Schaeberle's Companion of Procyon. Schaeberle's Companion of Procyon. Schaeberle's companion of Procyon is a far more difficult object than the com-panion of Sirios. It requires the best condition even to see it. At the present measures, though difficult to observe, it seemed to 1 Prof. 1struard to be brighter than for some years past. The hexagonal vation, and was invertably used. companion is now perhaps slowly closing in on the bright star, as indicated by the If this is true, observation of it will become more difficult and perfavorably placed in its orbit. The angutar motion of the small star seems to be increasing somewhat and is now betw 5 degrees and 6 degrees a year. ing are the measures of Schaeberle's com-

# The Current Supplement

Tills week's issue of our Supplement brings an article of nunsual import ance and interest from the pen of Prof. Birkeland, who has become famous as the foremost among the rather small body of men to whom the new industry of the manufacture of nitrates from the air owes its existence. Prof. Birkeland bas achieved greatness not only in the world of applied science, but also in the prosecharacter. For some time past he has been conducting a remarkable series of experiments in which he has reproduced on the laboratory scale certain ph observed on the sun, such as the co the sunspots, etc. His article on "The Origin of Worlds" is one of the most remarkable publications which we have had ecasion to place on record for some past.—H. F. J. Porter writes on life has ards in crowded buildings and the means to be employed to reduce such risks to a minimum.—A Diesel engine of French manufacture is described.—Dr. J. J. Dobbie tells us of the services which the sp troscope has rendered the organic chemi

# **Co-operation** and **Enthusiasm**

are evident in the response which our subscribers are making to our request for the names of people that would interest.

This is gratifying to us not only because the co-operation of our subscribers is of the greatest assistance to us in increasing the circulation of the "Scientific Ameri-can," but also because it shows that the improve-ments made in the publication meet with the hearty approval of its readers.

As a result we have materially increased the circula-tion of the "Scientific American" and have had the pleasure of extending the subscriptions of a large number of our friends who sent lists to us. Have you sent us a list? If not

## Here is the Way:

Simply send us the names and addresses of the people you think will be interested in the "Scientific Ameriand we will do the rest. An accurate record will be kept of all names received in this manner and for each new subscription we get from any list we will extend the subscription of the person who sent the mames to us for four months. Thus if we receive three new subscriptions from any one list the subscription of the person who sent us the list will be extended for a full year.

Of course, you may send as many names as you wish, the greater the number of names you send the larger the number of subscriptions we will probably receive and the longer the period for which your own sub-scription will be renewed.

Be careful to write the names and addresses plainly and don't fail to put your own name and the address at which you are receiving the "Scientific American on each list you send.

Address all lists to the Circulation Department, Scientific American, 361 Broadway, New York City.

The folior is always glad to receive for examinable illustrated articles on subjects of timely interest. If the photographs are shally the articles wind, and the facts authoritis, the contributions will receive shorn attention. Accepted articles will be paid for at regular space rules.

The purpose of this fournal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

#### Panama Canal Architecture

The reasoning to learn from the last bear of the transma Conel Revord that the urchitectural features of the Phanna thank, both as to landscape and buildings, are in the hands of an architectural firm of note, the character of whose past work is a guarantee that the Phannan Caual is not to be belifted by anaster architecture.

Too often in the next American engineering works to maximize have suffered either from devenued or missuprehension of their architectural and aesthetic requirements. The outlines sum amount of the strictly utilization principles of design which govern the captience are frequently intarquations and displaying to the eye, and do violence to an aesthetic sense whose demands are becoming more holstent with the general spread of knowledge and artistic education. Somethies, so is the case of the Brookh Bridge, a great engineering work is as ornimental as it is meaning the summarine and the case in the Williamsburg Bridge—surely the uptlest structure of its kind in existence—the result is artistically deplorable

succe-the result is artistically deployable. In our issue of February Sh of this year, we drew attention to the fact that the Yuanama Chaul was in danger of being designed by the crude character of some of the structures which were being creefed, and to prove our contention, we thinwrited a range or light tower, which had been built our the center will of the take approach to the father Locks. This structure, designed in the offices of the engineering force at the bulmans, is no dendi strong, stable and perfectly adopted to its purpose of showing a light by a certain location at a fixed elevation for all that to come, but considered as an architectural work in its about as agily and hope the structure of the content of the proposed showing a steel many content of the proposed showing a steel many content of the proposed showing a steel proposed in the content of the proposed showing a steel proposed about replaced, either is in more graceful design in the influence concerned, or live a steel more of open work construction similar in general multing to the Effect frower. We understand, however, that any change in this direction is strongly opposed by the engineer in this direction is strongly opposed by the engineer in

The Schwitzie America commonls the mittee to the sections attention of the chirmon of the latimion Count Commodom, to the longer that he will authorize the expenditure of the relatively small amount of money that will be necessary to remove the present structure from its very conspictions position and put in its place something that would be consistent with the dignity and great excellence of the engineering work at the Gatum backs.

## A Suggestion for Suburban Traffic

N a tetter in the New York Trace, Mr. W J. Wilgue suggeste a northed by which the capacity of the ratiroads which carry a large communer trafficlate and out of our office might be rendered capable of handling a larger number of passequers, on a more frequent schedule, at higher speed, and at a considerably reduced rate.

ably reduced rate.

The proposal carries additional weight when it is known that Mr. Wilgans was the oblef engineer of the New York Central Ratirond, who first proposed the utilisation of the "air rights" of the company's terminal grounds, by building a double deck station, and covering the space above with business and other city build

luga. He now proposes that the ratiroads should further utilize their air rights by building above their surface express and freight racks, elevated arriculuse reserved for a high-meed, electric, suburban service. The railroads that councer our cities with the outer world, sups this authority, have not as yet seen the wisdom of departing from the time-honored causion of utilizing the surface only of their leads for tracks. The result of running over these trucks a betterogeneous mass of trains—express passenger, local passenger, and freight, is that the express and limited rains are given the right of the road and commuter and freight trains have for drag along as best they may. This intermingling of traffic has produced such dissatisfaction among the commuting public and shippers of merchandise, that many railroad managers have publicly declared that they wish they might be suftrely releved from the obligation of serving sulturban commuties.

Another difficulty is that the concentration of local travel within the rush hours of night and morning coults in the railroad quant heing rarely used to more than ten per cent of the full cupacity; which, in turn, imposes the need for comparatively high fares with

imposes the need for Comparatively again times with which to pay unproductive Racic charges. The construction of separate overhead tracks would not only lengthen the distance to which the commuter could travel within an hour's time, but, though suffiable cooperation with municipalities, the old-fashioned concentration of travelers at congoned terminal contest might be replaced by a system of murginal subways, or sevurded routes, that would permit of a roady circulation of travel in the cities, with frequent stops in the business and manufacturing coulers. To cheepen the cost of sevice, a graduated range

To cheapen the cost of service, a graduated magof farce is suggested for the different hours of the day —comparatively high rates in the rush hours, with lessending charges before and after such hours, with lessending charges before and after such hours, with vollings shates that an increase from ten per cent of the rallrand's twenty-four hour enpacity to 20 per cent of the rallrand's twenty-four hour enpacity to 20 per cent of would cut the fixed charges per passeager in laif and reduce the total cost by some 25 per cent. By thus separating the commuter from the header and more ponderous trunk line service, by affording mobstructed recludation of runks in the clies; and by graduating the farce so us to distribute the "peak" or highest load of traffic over longer perfoles of the day, the rapidity of suburfant service would be herensed, the cost would be decreased, and a larger number of city workers with their families could live among more congenial and heulthful surroundings.

#### Is the Supremacy of the Battleship Challenged?

The present stage of the development of naval warfare the battleship is supreme, or to speak in our own more consecratively. It is believed to be supreme, in our own may, at least, it is believed to be supreme, in our own may, at least, it is below that in spite of the high degree of perfection to which the other various units of offensive and defensive warfare have been carried, the sense of a naval campiatic onto dedultely decided, only when battleship is timed up against battleship in the final supreme test

Now, nithough the general proposition that a naval ar can only be won by the destruction of the enemy's buttleship flett is undoubtedly correct, it is not countly certain that battleships can be destroyed only by bat-tleships. So great has been the development of the existing smaller units of wurfare, and so pregnant with possibilities are some of the newer means of attack, notably by the aerophane and the dirigible, that the quess us to whether the linal outcome of a naval campulan lies so completely with the battleship fleet us is commonly believed. Thus the torpedobout de-strayer hus developed in size, speed and efficiency to a point which entities it to be cuited not the torpedobont—but the buttleship-destroyer. Destroyer fleets are now composed of bonts so fast, so seaworthy, and so ubty hamfled, and they are employing tactics and de-vices so novel and bewildering to the enemy, that the time has gone by when they have to wait for the cover of alghi or fog in order to make a successful attack at close quarters. It was only last year that our daily press reported a successful attack by destroyers on a buttleship fleet, unde under the bright light of a noon-Under the methods employed, the destroyers emseives stemming at thirty knots parallel with the buttleship line at a distance of not over 2,000 yards (which is point-blank torpedo range), and they were doing this with a clear vision of the position of the enemy's individual ships, and under conditions which rendered it impossible for that enemy to locate the position of the destroyers or deliver any effective fire against them

against team. During a recent interview with a German naval officer, the statement was made to the writer that sithough the great susperiority in battleships of the British anyy would reuder it likely in the eventuality of heatilities that the Herman navy would be crushed, the high degree of efficiency of the German torpedo facet was such, that the victory would be went at a cost

which would relegate the British fleet to seemed the smoon the world's navies—a result which we seemed added to be entirely possible.

Comment.

adder to be entirely possible.

Another of the tesser units of warrars which is boiling chattenging the latticellip supremacy is this submarishs chattenging the latticellip supremacy is the submarish except have proved that the submarishe is saids, asserting the submarished character have proved that the submarine is saids, asserting the saids of the submarished character is said to the said of the

And new comes ReserAdentral Fisk with his bold proposal to substitute the 50-mile secoplane for the 15-mile submartine. Fisk would carry the torpedo strapped below the body of the ascoplane. From which it would be dropped by releasing a inteh. In delivering the atracts, the aviator likes at a high elevation to within point limits range of the battleship. Be then swoops rapidly downward to within ten or affects feet above the water, directing his flight so that on reaching the proper clevation, the torpedo bears true on the target. The fatch is thus released and the torpedo engine, started by the act of releasing, drives the missile straight for the mark.

Now every gunner knows how difficult it is to judge a range that is emplify changing hold its vertical and incircular particular that the aeropiane during its deamand right would be a matter of june good had the value of the particular that it is a superior of the the range-setter, and any gunner must admit that, if an aerophane could be built of sufficient power to carry a torpreb in the manner proposed, such a form of attack would present great possibilities.

This surfice must not be taken as a pies for reducing the size, min-nower or weight of armor of the present battlethit. We must most displacement with displacement, speed with speed, and gan wills gan, if we are not to be found wanting in the day of trial. The next five years will see a remarkable development in the three methods of attack above outlined, and it will take unother battle of Tsushima to determine whether our present. "Newndas" and "Pennsylvanias" are the lesst types to meet the average conditions of modern surface, or whether three must be a revision of types, such as resulted from the lessons of that famous consistent means of Japan.

#### Experiments in Electroculture

HE situatistion of plant growth by means of electrical curronts has now been carried on over a period of 167 years; and to this day it is hard to point on an tanglie and consist applicable results of these investigations, nor has this mode of cultivation yet entered into the ecclustrations of the ordinary agriculturist or hortculturist. In a voluminous work on electroculture recently published by Jir. A. Bruttini of Rome It is stated that 187 persons are knewn to have carried on experiments in this field. Of these, 133 reported favorable results, 21 were doubtful, while 33 found the sphileation of electricity to plants to be distinctly unfavorable. A majority of the first group employed more or less unceintified or superficial methods. Nevertheless electroculture continues to be the cherished dream of many present-day experimenters, as is stincessed by the fact that an "international Conservation of the contraction of the cherished dream of many was held at lithems last

Micrometer Observations, of Phaebs, the Ninth Satellite of Saturn.—In No. 4655 of the Astronomische Nochrichte, Prof. E. E. Barnard of Yeekes Observatory publishes the results of observations made with the 40-inch refector at a time when Saturn was 26 degrees higher on the meridian than when the stellite was sought for on the night of December 8th. After making a sketch of the 5½ 664. Prof. Barnard states, "I began measuring the Saint stars. It was then noticed that a star marked J4th magnitude, close north preceding a 12½ magnitude star was changing its postion. This proved to be Phoebe. A similar case occurred on December 81st, when I had marked 1t 14th magnitude on a statch and measured a much fainter star for the steellite." Prof. Barnard coordines that when the seeing is good Phoebe must easily lave been as bright as the 14th magnitude. "Under stalls are conflictions it should be observable with moderate absol instruments." Prof. Barnard states that the attellite is following almost in other cases.

Atr Ser Submariasa.—The use of peroxide of sodium for renewing the air in the confined quarters of aumarines, which was first promoted in France by Profs. Desgrees and Balthasard in 1897 and since then adopted in the British anny, has been labely tried with oxylithe on board the submarine "Argonauste" of the French fleet at the navel scatabilishment of Toulon. On this coession the submarine remained under water for 12 hours. It contained a crew of 21 officers and men, together with the two members of the testing commission, and the results as a wholes were recognized to be excelled

Pretecting Iren and Steel from Corrosion.—In an industrial note United States Consul Albert Haistead of Birmingham tolls of a process for protecting iron and steel from corrosion which was called "ferro-nincing" or 'ironizing" and is a coll clotter process. It is claimed to be suitable for coating plates, angles and channel from built up structures, tubes and cylindrical vessels, boils and nuts, small eastings and forgings. It is said to be cheaper than other similar processes, the cost being dependent upon the nature of the articles and the thickness of the coasting required.

A Tidal Ferry.—A new type of steam ferry has lately been put in use at the port of Hamburg. It somewhat resembles a craft used in England for a few years past, and is obarceterized by the fact that the main deck in movable and ona be raised or fowered by as much as 15 feet, the deek being strong enough to carry six large basiing wagons. The daily variations in the tide level at Hamburg made this kind of foreyboat necessary. Of 170 tons displacement, the new ferry is 120 feet long and 50 feet wide and carries triple-expansion engine giving 650 horse-power. When the boat enters the wharf is omes into a small and completely sheltered does

Treaty-seven Miles of Subway Constructing.—Tho last report of the Public Service Commission for the most sending June 18th shows that eighty-ne million dollars is being expended on twenty-sevon miles of the New York rapid transit subway. Since practically all of it will have four teachs, it can be said that about one hundred miles of single track is under construction. The number of the subway of the subway of the property of the subway of the subway and the center with subway and the Center Street loop between the Williamsburg and Brooklyn bridges are presticable ycompleted.

What Might Have Been.—A striking comparison is drawn by our contemporary The Nawy between our foreign trade earried in American ships in 1826 and to-day. Attention is drawn to the fact that if the water-borae foreign trade of the United States were per capital equal to that of Great Britain is would amount to \$14,-00,000,000 per annum and if our foreign carrying trade in American ships were the same proportionately as it was in 1828, when it was 90 per cent of our total foreign trade, it would amount to-day to \$12,000,000,00. Last year, as a matter of fact, it amounted to only \$322,461,556.

Two Thessand Engineers Wanted.—Attention is drawn by the Engineering Record to the fact that the recent act of Congress suthorizing the valuation of rail-ways institutes a work so large that probably about two thousand engineers will be needed to fill positions ranging from those of a minor character in field parties to the responsible work in charge of divisions. All of the positions are to be filled through civil service examinations. Engineers with the necessary testing will find it to their advantage to give the forthcoming examinations careful consideration. The salaries padd for this work will probably be at least as high as those paid by the railroad companies for similar work.

panies for similar work.

Death of a Well-knewn Shiphailder.—The recent death of Edwin S. Cramp, formesty vice-precident of the William Cramp & Sons Ship and Engine Suiteding Company, the second son of Chartes H. Cramp, marks the cash of another member of a family that will always be famotes in the srinals of American chipbuilding. It was hig grandatable, William Cramp, who founded the large shipbuilding plant on the Dalaware Elver. In these years through the company of the company of the company of the transition of the company of the comp

#### Electricity

High-frequency Generator.—According to recent pressing attended, an English segiment, William Durtual, has invented an electric generator designed to produce heavy current with an alternating frequency of some 30,000 to 100,000 ceellistons per second. If this between the contract should play an important part in wireless telegraphy and telephony.

graphy and telephony.

Bird Perchas on Line Poles.—In the rules and regulations for bare transmission lines, published by the German Association of Electrical Reguneers, it is presentised that the poles and eross arms of transmission lines bus of designed as to provide no footing for birds. In carrying out this regulation a German firm has designed a pole provided with a perch at the top on which the brade may roost. The perch is merely a T projecting from the pole proper, the latter being provided with a conical cap, so as to aford no footing for the birds. While the brackets and cross arms are not absolutely devold of rooting places they do not offer as attractive a perch as the T at the top of the noise.

An Electric Lamp for the Dark Room can be placed very conveniently beneath a transparent jease dish for use in developing plates. Photographers know the inconvenience of having constantly to remove the plate and hold it up to the tight to see whether it is finished. This can be avoided by certaing out a square opening in the bench, covering it with a glass plate, then putting one of the usual preased glass trays upon this as a support. Under the table is an electric lamp arranged to give a red light. A somewhat strong light can be used, fisshing it on momentarity by a foot or the plate of the plate witch. The usual dark-room lantern can also be retained, putting on one or the other light when need be.

Wireless Determination of Longitude.—In a paper read before the British and Prenoh electrical engineers at Paris, Commandant G. A. Ferrer described the system employed in sending out time signals from the Effect lower, whereby even an unskilled person can estimate how much his clock or watch is fact or slow to within half a scoond. He also described the recent experiments conducted between the Eiffel Tower Station at Para and the Arlington Station at Washington to determine the difference of longitude between the two otties. The experiments are to be resumed next fall, and by using photographic galvanometers with rapid vibrations superimposed by a uning fork, it will be possible to measure to within 0.001 second.

X-ray Moving Pictures.—Moving picture views made with the X-rays are quite a novelty, and the German scientiat Descuer now succeeds in producing them by an apparatus of his make which gives such powerful X-rays that be can take six photographs a second in this way, and he works a cinematograph which shows the movements of swallowing, the throbbing of the beart, and the like. The apparatus for producing the powerful X-rays employs an improved current breaker in the primary of an induction coil which gives rapid break and enables him to secure secondary current from the coil of much higher power than usual. Using this device in connection with an X-ray tube he obtains rays which enable sharp and rapid radiographs to be taken.

Direct V. Alternating Current Between Trelibetton

Direct v. Alternating Current Between Treithasten and Copenhagen.—In estimating the cost of generating and transmitting ourrent from Treithasten to Copenhagen a three-phase, 010,000-voit lime and a direct-current \$0.1000-voit law and a direct-current \$0.1000-voit system were considered. The latter which called ro 20 generators in series, under the Thury constant-current system, was found more economical and was adopted. Its chief advantage lay in the ability to transmit current under water without transformer stations, two cables being employed instead of four cables as would be required in the alternating scheme. The alternating system would sail for three transformer stations and a frequency-converter station, conversing from 25 cycles to 50 cycles. Ascording to estimates made, the continuous current system abova a saving of \$400,000 on the annual cost. The distance from Treithasten to Copenhagen is 204 miles. three miles of which I under water.

New Electric Lecomotives for Swins Railroads.—The Swins Federal railroads are non to make use of two electric bosomotives of a new type which are now in consciuntion at the Brown-Bowed works and are intended to work on three-phase current. The new locomotives have two newly-designed electric motors of 1000 horse-power size. Four driving axies are used, with driving wheels coupled on a new system, and this allowed raising the motors on the locomotive track so that they can be more resulting imported than herestofors. This also raises the center of gravity as experience shows to be necessary for good running. The trush has two non-driven axies. The driving wheels are 4 feet 2 inshes in disansets and he file wheels 2 feet 8 inches. Four speech are given the locomotive by medifying the number of pairs of poles in the motor by proper sheeriest conscious for giving 6, 8, 12, and 18 pairs as as to run at speech screening and 45 miles as hour. The locomotive can develop as high as 2,800 horse-power at full speed.

#### Automobile

Kerosene Taxable Abroad.—Whether keroseno as motor find ever is taxed in England, as several times has been instell would be the case, the possibility is at least likely. The Home Secretary recently has stated that under present laws it is taxable under the definition of motor spirit, provided it comes into general use and gives evidence of proving reasonable, officent fued

Berlin's Motor Cabs Increasing. Recent traffic returns for the oily of Berlin indicate that the number of motor cabs at present in service is 1,218, as compared with 1,050 a year ago. On a like basis of comparison, the horse-drawn variety numbered 3,288 a year ago and 2,773 at present. In other words, while the number of motor cabs increased by 153, the number of horse-drawn cabs docreased by 252.

Killing Two Birds With One Stone.—In line with the clever foreign practice of combining the manufacture of motor cars with the production of eventy machines and guns and what-not, one British dealer has developed an unusual scheme for reducing 'overlend express." He uses his demonstrating cars also for hire purposes and in this way makes them pay the expense of demonstrating, which in many cases is high.

Supplying Steam to Carbureter.—Patent No 1,050,-967, granted to Harry A. Babbatt of lattle Rock, Arkansas, provides means by which steam may be injected into the carbureter of an internal-combustion ougher for increasing the efficiency of the explosive charge and regulates such supply of steam, the steam houge derived from the overflow water from the jacket by heating it by the exhaust

A Gasoliae-electic Truck.—A somewhat novel Kurpena combassion is that of a power wagon and an electric-ear truck. The truck is designed so so to allow of carrying the loaded power wagon bubly and thus transporting it over the traumay rais to the radroad depen, where the load is charged upon the militand rans, then the empty wagon comes back by the traumay as before. This effects a saving in war, for the distance from the place where the wagon takes ou the merchanduse, to the traumay, is comparatively short. All that is needed is to modify a car truck by putting on a pair of larged channel bars in the rese which can be let down so as to form skeds upon which the power wagon may be drawn up by means of a winch.

Motering Increasing in Switzerland.—Despite the numerous obnotions law that have been leveled at the heads of motor tourists in some parts of the republic of Switzerland, recent returns show that the number of tourists visiting that country increased during the past year instead of dimunshing. Altogether, some 9,000 automobile tourists centered switzerland, the average stay being calculated at 13 days, and 11 is estimated that their exponditures approximated \$3,000,000, which is an increase of nearly 33 per cent over the expenditures for the previous year.

Effect of London Taxicab Strike.—Although the striking drivers of London taxeabs, who but recently have returned to work, had all their demands acceded to, it probably will be a long time before the industry returns to its previous stable basis. During the time the easier not running, the publish became more cognizant of the real value of London's oxedlent time and 'bus service; the result is that there is evident the station to pay the beaver toll of the taxical men and no memospherable number of the metropolis's 8,000-odd cabs are running fraceloes.

Novel Corner-lighting Scheme.—One regeneous metorist with a penchant for trakering has evolved a novel and simple apparatus for easting the light beams from his bead lamps around a corner. The apparatus consists of nothing norse complicated than two strips of height tin vertically supported in front of the lamps in matter saviveling brackets. The front cands of the strips are connected and from the connection a wire-leads to the steering column. Hence, it is a sumple matter to true the tin strips either one way or the other, depending upon the direction of the road; and as the strips normally are in the same plane as the light beams they do not reduce the efficiency of the lamps appreciably

Where Standardination is Needed.—With the present method of diving speed-whetening instruments, the indicating needle shows a tendency to assultate so rapidly as to make accurate reading difficult when the ear a driven at speed over other than very emonth reads, and this feature suggests that a better method of driving them is possible. When the matrament is driven from one of the front whosts, as it the present general practice, the bouning of the whost, with consequent sight; symming, is reflected mutantly in the meter. At least one munique, is the successible of the standard of the standard of affixing the driving gear to the propeller shaft, and has action points out wherein a material improvement in mounting and driving can be made. Such a location requires a lose facilities that that does the front wheel driving method and the shaft itself is less liable to be broken through acodesia.

## The Arches of Mexico

## Relics of Early Spanish Engineering

By Mary Worrall Hudson

I'll will be a sorry day for Mexico when the arches that were ball by the Spanish conquestadors, their descendants, and their Indian slaves, are destroyed or permitted to fall into decay.

Now all over the country, the traveler whose eye is attitued to beauty is dollarled with the springling arch, the true teauty line of architecture. The arch in Mexico is often moselve rather than light—even countersome, periaps; but it is a wiway spraceful. Many of them make up in missoury what they lack in selentific proportion and construction, like the

and Roman arches but by this means then may soon for the centuries, and will be a grateful relief to the landscape for as man more if they are pountfied to endure so long. There are articles in Mexico that rea is true as architectural principles could make them, and anot are leng built in many parts of the Republic, but R be for the preservation of the old and the pletture-sine that a plea should be succeeded in once. simulacra of the natural gem have attained, some at them almost defying detection save under the class accutiny of the keenest experts.

Hence an account of the methods employed in their making as described in Les Anneles is exceedingly in

The simplest forms are uniformly apherical and assumerely giass balls blown by means of tweet of varying size. More ingenious and more natural-looking are the irregular perits or peries poirregues. To produce these

the workman sometimes merely touches the ball momentarily with the end of a red-set tube, thus melting the glass at the point of contact and drawing it out irregularly. In other cases he touches one spot or another of the ball to a fizme, at the same time blowing gently in he tube.

The ball is pierced by two holes, one of which is caused by the treath of the workman, and the other by the hollow in the tube at the moment when this is detached from the pearl by means of a slight

These balls are then merely costed inside with a preparation known as "essence of the Ortent." This, despite its claborate title, consists merely of pure water holding in solution the scales of the little fish known as the bleak-fish.

Artificial pearts were unknown till 1656, when a French jeweice named Jaquia, who was fond of angling, noticed that clear water which had been need to wash bleak-fash ("Opprisus allowresse) contained a sticky deposit consisting of the beautiful shining scales of this little fash.

The first efforts to use this in simulating pearls consided in conting little balls of plaster or similar composition with it. But the conting quickly wore off, giving the "pearls" a overy aspect. Attempts to make hollow beads and apply the conting to the interior were more successful as to beauty and permanence.

beauty and permanence.
The operation consists in the sucking
of the liquid into a tube drawn out to a
fine point and then blowing it into the
glass bead, which is then given a rotary
motion to surend the coaling sevent

motion to spread the costing evenly.

The bests when costed are placed in a sieve whose bottom is covered with parchment and shaken incressantly till dry. Finally they are filled with wax so

as to be less fragile and a little heavier.
To produce beads of ultra-flue quality
and remarkable sheen, skilled workmen introduce traces of an exceedingly fusible
and volatilizable metallic alloy.

The glass employed is of a specific composition, specially manufactured for the purpose in the form of long tubes or rods.

## Lanthanium and Bacteria

structive plans of practice battleship for naval militiamen

and of model buttleships that can be made to turn and counter-

"The Merit System in Road Adminis-ation," will form the subject of an address by President John A Melihenny of the United States Civil Service Commission, and will undoubtedly stiract nation-wide altention. Political favoritism, incompetence and indifference characterize the administration of our public roads so generally as to cause a loss estimated by some experts as high as \$40,000,000 a Mr McIthenny's paper will show the demoralizing effect of political dom ination in road management and point the way to an efficient system which will ean skilled supervision, continuous and practical service and due economy.

#### Hardening Fats by Catalysis

IN many industries, such as the making of soap and stearin, and the manufacture of various edible fats, the firm hard fats are more prized than those which are soft, lardy, or olly Hence a means of bardening the latter has long been sought

After many failures success has been recently achieved, so that it is possible to change the soft and liquid fats or oils into hard fats with a correspondingly high melting point.

In principle this consists in the intro-duction of hydrogen into the fluid fatty ucids contained in the soft fats and olis This depositing of hydrogen takes place.

according to the Technische Rundschau when the fats are warmed in the presence of the se-called contact-bodies. Nickel Nickel and pailadium are especially valuable as such cutalyzers, either in the pure puiverized state, or in the form of aqueous solu-tion of various salis of these two metals

The fat to be solidified is warmed with about one fifth per cent of the metal powder or the solution, the temperature varying between 100 deg Cent and 300 deg Cent, for different futs and different Then bydrogen is led in at the highest temperature required, and when ssary the reaction is hastened by in-sing the pressure 2 to 3 atmospheres

This process is long past the laboratory stage and has been applied in various industries on the large scale, and has been found economical as well as useful.

An advantageous feature is the destruction both of coloring matters and of mal odorous substances in the fair treated, so that a long series of previously inevitable purification processes is avoided.

This method will doubtless soon cause revolution in the industries involved, and will incidentally extend the market

#### A Case of Latent Life

A REMARKABLE case of animal leth-argy or latent life is found by M. Issel among the small crustaceans (Harpacticus fulous) of sea ponds. The water of these pools, which lie near the shore, undergoes great variations in amount of sait, being diluted after min and concentrated in dry periods so much as to deposit sait on the bottom. During high tides, when the pools are filled with a fresh supply of sea water, the crustaceans are very active and cover long distances by swim-ning, but when the sait solution becomes concentrated, their movements are grad ually slower, and finally they remain on the bottom apparently dead. But this is in fact only in appearance, for when he transported the inert animals to a less concentrated water as ordinary sea water. they revived in a few minutes and began to swim actively. M Issel calls this unal phenomenon osmotic lethargy, to distinguish it from the lethergy produced by desicention or cold. As to how long such latent life would be maintained, he collected inert specimens and placed several of them in sea water each day to ravive them, and found that after 17 days

# The Reflector—The Telescope of the Future

## Why the Large Refractor Must Give Way to Mirrors

By Edward Arthur Fath, Director of the Smith Observatory, Beloit, Wisconsin

THE rôle of prophet is by no means an easy one, and many a prophecy falls of fulfillment because of the totroduction, at a later time, of previously miknown inctors. In spite of this difficulty, however, I shall attempt, at the request of the Editor, to tell why I believe the reflecting telescope will be pre eminently the escope of the future

In the beginning it may not be out of place to recall ssential difference between refractor and reflector. The former is the one usually called to mind when we think of a telescope It has a lens at the upper of a tube through which the light passes. At the lower end is the exeplere through which we look. On the other hand, the reflector has no lens, but a large concave mirror which takes the place of the lens mirror is placed at the lower end of the labe, the latter being open at the upper end. The light passes down through the tube to the mirror, is reflected back to the upper end and brought to a focus where the eyere or photographic plate is placed

There are four points to be considered in planning for a telescope. Original cost, maintenance, efficiency and adaptability to various classes of work. Let us compare the two types of telescope under these heads. Original Cost.

Under this division we shall consider two telescope of three feet aperture The Clarks re-

ceived \$50,000 for the 36-Inch lens of the Lick Observatory and a mounting similar to that would cost about an equal amount. Thus this large refractor may be considered to represent an estment of approximately \$100,000

Now compare this cost with that of a reliector of the same aperture. It is possible to obtain a 3-foot mirror for about \$5,000. A sultable mounting can be had for about \$15,000, or even less if a very simple design is chosen equipped reflector would therefore cost in the neighborhood of \$20,000, or approximately one fifth that of a re-fractor of the same size.

For telescopes of this aperture, which must be permanently mounted and properly protected from the weather, on additional item must be considered, namely, the cost of build ing and dome. The reflector can be made much shorler than the refractor so that a dome with a diameter of 40 feet is ample for a 3-foot instrument of this type, while the great Lick re

eter of 75 feet. Since the cost of domes varies approxi-uately as the cube of the diameter, the refractor dome would cost over six times as much as a similar struc-ture for an instrument of the other type

It may therefore be said that, in general, the properly housed refractor of large size will cost at least and possibly six. times as much as a reflector of the same aperture. For smaller instruments the ratio may be even higher.

Maintenance.
Barring an occasional dusting of the front lens surface and possibly the work of washing it once or twice a year, the refractor requires little care. The reflector however needs occusional renewing of the silver flux. The frequency with which this is necessary depends mon the location of the instrument and the care with which it is protected. If the writer has been correctly informed it is necessary for a certain large reflector to be reslivered about once a month the large amount of smoke and combustion products in the atmosphere near its location. At the other extreme probably stands the Crossley reflector of the Lick Observatory The silver tilm on the mirror with which Keeter obtained his famous photographs of the nebulo, was over five years old. Under ordinary condi-tions we may say that resilvering about twice a year is all that is required for a telescope in regular use The slivering process is by no means difficult and taken but a comparatively short lime. Thus the 60-inc mirror of Mount Wilson can be taken from the tele Thus the 60-inch scope tube, restivered, and uprin be out into position in a day. Smaller mirrors can be altended to in much

Ordinary changes of lemperature have but negligible effects on the performance of lenses, while mirrors are very susceptible to them. It is therefore necessary for the most reflued work with large mirrors to have some arrangement for keeping them somewhere near the night lemperature. A small refrigerating plant is used nt the southern station of the Idek Observatory at Santiago, Chili, while an insulating cover of woolen blankets is provided for the 60-inch mirror on Mount

Efficiency.
It is probable that from the standpoint of visual observation a good refractor will give somewhat bett definition than a reflector of the same size. best of the writer's knowledge no really definite tests to determine the precise difference between the two types have ever been carried out, but the few trials actually made give the refractor the better of the argument. In theory there should be but little differ-

Visual observations, however, are by no m important, relatively, as they were 25 years ago. At that time practically all observations were visual, but now I believe it is not far from the truth to say that faily three fourths of all modern astronomical observailons are photographic. At the Mount Wilson Observatory not one per cent of the observations are visual,

There is no question whatever that the reflector is far beiter photographic instrument than the refractor;

Diagram showing relative size of structures required to house two telescopes of the same aperture, but of different types.

for it brings all the rays of light of whatever color to focus, while the lens of the refractor do it therefore seems only reasonable to use the instrunt lest adapted to modern conditions.

This freedom of the reflector from sunrious color effects is also of value in visual observations, particularly in the sindy of the colors of the siars and in work on the planets. It is so marked that a voteran observer, who has used the two largest refractors in the world and also the largest reflector in operation. recently told the writer that for work on the planets

he would without hesitation choose the reflector.

There is another point, however, which must be con sidered under the heading of efficiency. Telescopes are ever increasing in size. In order to have a lens or mirror perform well it must be supported in such a way that the flexure due to its own weight does not injuriously deform the optical surface. A lens must be supported from the edge. There comes a time when an increase in size will add sufficient extra weight to produce appreciable deformation and thereby injure the performance of the telescope Certain tests made the 40-inch lens of the Yerkes Observatory lead to the conclusion that it would not be advisable to to the conclusion that it would not be averaged in make a refractor of larger size unless a new way of supporting great lenses is found. With a mirror, nower, it is possible to have the glass of sufficient thickness to be fairly rigid and then have a system of supports so designed as to support the entire back of the mirror and thus completely prevent flexure. Furthermore, the larger a lens the thicker the glass.

This means increased loss of light due to absorption. That this is really a serious matter will be realized when it is known that the great Lake and Yerkes lenses transmit only about 50 per cent of the photographic

This is termed the chromatic abstration of the lens.

rays falling on them. This loss is due primarily to absorption. Doubling the size of such a lens would about double its thickness and it would therefore transmit only about 25 per cent of the actinic rays. This means that while the lens area has been increased four times the amount of light reaching the image would only be doubled. Now the silver film of mirror in good condition reflects about 60 per cent of the photographic rays. Therefore by doubling the ape ture of a mirror, the light reflected is increased in the same ratio as the area or four-fold. for large instruments, the reflector is the more efficient in its light-grasp.

Adaptability

A refractor is not well adapted to most kinds of direct photographic work. It can, however, be used for both visual and spectrographic observations. On the other hand, the reflector is well adapted to visual work and is at its best in spectrographic and direct photographic applications. It is therefore the more universal instrument.

Thus far the point of view has been that of the working observatory. Let us now take the amateur into consideration. The average individual of this class is not blessed with a superabundance of this world's goods and he therefore usually buys the optical parts of a telescope and makes the

mounting himself. Suppose such a person wints a telescope and must ch between refractor and reflector. What shall be do? If he will experin little until he is not afraid to do his own silvering the writer believes he will feel much better satisfied with a reflector of from 9 to 12 inches aper-ture than with a 4 or 6-inch refractor costing about the same amount. The jects us well us their true colors, and for surfaces such as nebulae the image will be brighter for the same magnifi-

However, the great consideration in this connection is the following. Very few people possess the personner mathe cal training and mechanical skill required to make refractors for themselves, but many can, with the exercise of sufficient care, make very creditable reflectors. Thus, by means of their own handiwork, they may penetrate into the depths of space and see for themselves the wonders of the heavens. There has been so much published in

recent years on the making of reflecting telescopes that almost unyone, of average intelligence and suffi-

cent patience, can achieve this result.

A friend of the writer's recently completed a very satisfactory reflector of 8 inches aperture. The total cost, including a simple mounting, was \$6. The small flat had been given to him, but even if he had been obliged to buy it, the cost would have been but \$10 more. in the foregoing I have stated some of the more important reasons why I believe that, in general, the telescope of the future will be the reflector. ons may be summed up as follows: The first cost of the reflector is relatively low, and, while it requires a little more care tion its more aristocratic brother, yet this is a small item as compared with its greater

The Compressed-air Transmission Responsa.-Despite the rebuffs to which the compressed-air transmission has been subjected, two Frenchmen, convinced of its value, have brought out a car in which six is made the medium through which the power of the engine is transmission. mitted to the driving wheels. According to the system, the engine has four cylinders, set in a V, two of which act as pumps to compress the sir in a tank hung to the chassis. From the tank, the air is admitted to two other working cylinders direct connected to the rear axic of the car. In operation, the system works on the same general principle as do hydraulic transmissions, with the important difference, of course, that the air is a great deal n ant difference, of course, that the sit is a great deal more cleated than it she old in other yeatems; hence great dealms are made for the air system. At present it is being touted out, and though its efficiency, he not been demonstrated to be very high, it is expected that its simplicity and flast-bility will overcome the disadvantage of its insificiency. Enough air is stored to make the vehicle self starting.

#### Natural Toothbrush

To the Editor of the Scinwart American: Apropos of the paragraph on "Natural Tooth brushes" in your issue of June 7th, it may be of interes prusses in your issue of June 7th, it may be of interest to state that these are need by many of the people of our Southern States, chiefly in the rural districts. The graph of the black gum are those most in favor, while strips of thelk helouy, back are also used in the same wags or the bases guin are those most in a twor, while rips of thick hickory back are also used in the same anner. Users of snuff chew the end of the twig until nessumes a brush-like form, and then dip it into snuff, is then rubbed on the gums and carried in the mouth. have observed this frequently in Arkansas, and the gradies no doubt prevails in other parts of the South. Washington, D. C. PAUL R. BIRGE.

#### How the Public is Affected by Price Maintenance

To the Editor of the SCIENTIFIC AMERICAN

Two years ago the manager of a chain of Southern stores said to us: "We can easily sell Hoosier cabinets to our trade for \$10 more than the price you fix, and to our trace for ato more than the price you ha, and all we ask is that you keep your price list out of our territory. The Hoosier name is well known, and the cabinet is a much better cabinet than people can be a supple to the cabinet is a much better cabinet than people can be a supple to the cabinet is a much better cabinet than people can be a supple to the cabinet is a much better cabinet than people can be a supple to the cabinet is a much better cabinet than people can be a supple to the cabinet is a much better cabinet than people can be a supple to the cabinet is a much better cabinet than people can be a supple to the cabinet is a much better cabinet than people can be a supple to the cabinet is a much better cabinet than people can be a supple to the cabinet than people can be a anywhere else for the same money, so why shouldn't we be allowed to make the extra profit we can get

for it?"

When we refused to allow that dealer to fix his own price on Hoosier cabinets, he took up an unadvertised line of cabinets and is selling them for the exorbitant profit he wanted to make on the Hoosier. Our policy has been to limit the price of Hoosier cabinets to a small, fair profit, and to require our agents

cabinets to a small, fair profit, and to require our agents to stick to that strictly As a result, Hoosier agents know that they can rely upon this small profit on every cabinet, and they push the cabinets with confidence and success. They have made more profit on these ets than on a great many other lines of furniture eabinets than on a great many other lines of furniture on which the price fluctuates. The result has been an increase in volume of sales, which has lowered our cost of production and enabled us to put constantly more value into the cabinet. We have had a constant fight to keep dealers from pirating the good will our national advertising has built up, by getting hold of one or two Hoosier cabinets and offering them at a out

one or two Hoosier cabinate and offering them at a cut price, and then switching the prospect to some other makes of cabinet on which there was a long profit. Under the previous interpretation of the law we were able to stop this practice by Hmiting the sale of Hoosier cabinets to exclusive sgencies and strictly requ-lating the price at which the cabinet could be sold. With this restriction taken away, there is now nothing to prevent a dealer from offering Hoosier cabinets at a ridiculous price in order to draw trade from his competitor. He will not sell many cabinets at this public he will make it impossible for the competitor but he will make it impossible for the competitor to push Hooster cabinets at the legitimate price, and the tendency will be to throw kitchen cabinets into the class of "disorganized merchandise" that has been responsible for the chaotic condition of general furni-ture business in the past.

THE HOOSIES MANUFACTURING COMPANY, New Castle, Ind. E. G. McQuinn, Sales Manager.

#### Price Protection and the Consumer

To the Editor of the SCIENTIFIC AMERICAN:
Price maintenance is a highly important question
and one that will have to do very largely with
the economical purchasing power of a dollar in the near future.

We do not believe in a monopoly or in a we so not seases in a monopoly or in agree-monts regarding the fixing of prices by competitive manufacturers, but we'do believe that the con-sumer is more thoroughly protected when he pur-chases an article upon which the manufacturer has fixed a selling price than he is in the purchasing of an article that has not been standardised in

Our reason for making this statement is: First. Our reason for making this statement is: First. Because the nanufacturer cannot afford to establish a price that is too high or excellent received. Second. If he is assured that the acticle which he is manufacturing is to be restailed at a certain price, he is enabled to plan his product and distribution in the most economisal manurer, thereby tribution in the most connumbed manner, thereby giving the consumer full value for money expended. Third. Retailiers generally profer to handle standard: priord exticles, and they will tell you almost without exception that while they do not make at large a grount on these proofs as they do, as a large a grount on these proofs as they do, as a rules on ground which are not standardised, as accepted of the critically better material for the critical of the critical property.

作業を必要性は特別を行う。 マー・ファイン

given to their customers they find them more

given to their customers they find them more profitable to handle. Personally, I much prefer to go into a store and buy an article which is sold at an established price to everyone. As a manufacturer I feet that we would be unable to maintain the high quality of our product were it not for the fact that we wish. insist on prices being maintained at a certain andard. South Bend Watch Company, South Bend, Ind. S. D. Rider, Vice-President.

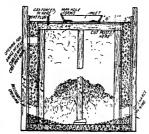

#### Practical Elimination of the House Fly

To the Editor of the SCIENTIFIC AMERICAN:

The case against the house fly has been so thoroughly and well handled that no further arguthoroughly and well handled that no further argument as to the desirability of eliminating this peat is necessary. The oriminal has been condemned to death. These undesirables, however, are so numerous as compared with the executioners that no impression can be made by this means of procedure. A great deal has been written on the subject, well meaning idealists have expounded their theories for years on the lecture platform, but so far the writer has been unable to find even the suggestion of any practical method which will tend to dimnish this pest. Therefore, let us get at the cause and see if it is not possible to destroy this insect before she can lay her eggs.

at the cause and see if it is not possible to destroy this insect before she can lay be reggs.

Every student of the subject knows full and thoroughly well that the house fly is hatched in stable manure; one fly will lay 150 eggs a day, the progeny of one fly during a sesson could multiply to the enormous figure of one hundred and ninety-five billion. If we attempt to destroy the larve, or the eggs, by means of saids or lime, we also destroy one of the most valuable

anure pit designed to facilitate the killing of files.

products of the farm. Lime will reiesse the ammonia in the manure and thus destroy to a great extent its fertilizing value. The same occurs when various acids are applied. So our problem is to preserve the fertilizing value of the manure and at the same time destroy the fly before she has

as the eggs batch, the larves work upward.
They never work downward. The habit of this
Insect can be well noted by observing any fly
trap. The bottom of the trap is always open. the fly's instinct is to work upward, it no

finds the opening.
Some philosopher has said that a problem well and thoroughly stated is half solved. I

Some philosopher has said that a problom once well and thoroughly stated is half solved. I have briefly stated the problem, and keeping in mind the institute of the insect, a solution for the elimination of the fly presents itself, and in presenting itself we also find a means of better preserving the fertilizing value of the manure. Up to the present time, this value has been conserved by the use of concrete manure pitc, thus retaining the liquids and therefore the nitrogen. Carry this idea a step farther and build a concrete stank with a covered top. The tank should be elevated in the top of the tank, we such below the present time top of the tank, a venthole consisting of \$5\time\$-inch or \$5\time\$-inch or \$\time\$ client he po, or a trap door in the side at the top, and two or more disabeter opening the control of the manure placed in the tank. The cover is immediately replaced over the manhole, and before the next two placed in the tank. The cover is immediately replaced over the manhole, and before the next bette is placed in the tank. The cover is immediately replaced over the manhole, and before the next bette is placed in the tank. The cover is immediately replaced over the manhole, and before the next bette is placed in the tank. The cover is immediately replaced over the manhole, and before the next bette is placed by the tank. The cover is immediately replaced to the tank. The cover is interested to the tank and the cover is the cover is the tank and the cover is the cover is the cover in the side of the tank and the cover is the cover is t

By this method, between the time each batch

is placed, the flies that are listaked are killed The larve hatch in a few hours, always work upward, and become pupe in about five days The discharge opening being at the bottom does not form an outlet for the fly, the liquids are all retained and the manure can easily be removed by long handled rakes or hoss, or if the tank is sufficiently large, a chann conveyor can be operated running across the bottom of the tank, pulling out the contents, which of course by gravity is stomatically replaced.

A circular tank 15 feet in diameter and 10 feet

high will hold about 60 tons of manue. Such a tank placed alongside the stable, at a level lower than the stable floor, serves the double purpose of conserving the fertilizing value of the manure of conserving the fertinging value of and killing the fly before she can lay an egg. The and killing the fly before ane can my an egg row size of the tank depends on the number of head of stock. On a large stock farm, such a tank of above dimensions would cost about \$80 and of above dimensions would cose and would more than pay for itself in one year.

ALBERT MOYER

#### How the Retailer and the Public Benefit by Price Maintenance

To the Editor of the SCIENTIFIC AMERICAN:

As a manufacturer who believes that his duty lies in serving the public, I wish to express my appreciation and approval of the stand which you have taken in regard to the right of the manufacturer to establish the price at which his product shall be sold to the con-

The popular conception of this matter, as held by the general public, is so erroneous and se inuical to their best interests, that I cannot conserve of any work which can be of more importance and of more service to the public as a whole than that of presenting clearly and concisely the true facts of the matter.

The main object of all unnufacturers is to place a price on their product which will enable the largest possible number of people to buy and use it and at the same time yield to themselves and to those who distribute their product an adequate and reasonable profit.

As volume of business is the thing most desired by

As volume of reasmess is the thing most desired by the manufacturer, and as he realizes that the volume must depend absolutely on the reasonableness of his price, the possibility of his setting a price which will be unreasonably high or yield himself or his dealers an everhilant profit is extremely small.

As a matter of fact, out of the several hundred trademarked articles on which has effort has been made to maintain the price by the manufacturer, I know of

no instance in which the price has not been lower than it would have been if the establishing of the retail price had been left to the unrestrained action of the retailer.

The main object of the retailer is to secure volume

and profit, just as these are the main objects of the seturer, but the retail dealer's ideas of the proper way to seeme volume and profit are very different from those of the manufacturer.

The average retailer believes in securing an abnormally large profit on the greater part of the merchandise which he sells, and trusts to seeming his volume by offering an abnormally low price from time to time on certain articles, which he believes will bring the people to his place of business.

ems to me that it is eminently unfair that certain people have to pay a very excessive margin to obtain certain merchandise that other people are able to obtain at practically cost as a result of this merchan-

With the right to establish re-sale prices once granted to the manufacturer, the abnormally high price and the abnormally low price are both eliminated from the scheme of retail distribution.

The relatiler, instead of securing 40 per cent, 50 per cent or 60 per cent gross on his retail price, as it is his desire to do on the majority of goods which he sells, must content himself with the normal 25 per cent or 331's per cent which the prices established by the manueturer yield him. Neither is it possible for him to cut the price on

this product to a point where there is no profit in it for him, where he undernmes the business of his competitor simply for the purpose of getting people into his store with the ridiculously low-priced article as a balt in order that they may purchase increased quanti-ties of the exorbitantly priced articles.

The educational work which you are doing will, I think, help to prove to the public that the greatest element in the high cost of living to-day is the excessive cost and profit of retail distribution caused by too fierce competition on the part of the retailer and a desire for too heavy a profit on his part, and that the only curb to this excessive cost of distribution has in giving the manufacturer the right to establish a reasonable price at which his product shall be sold NATIONAL VENEER PRODUCTS COMPANY,

CHARLES R. STEVENSON, General Manager. Mishawaka, Ind.

A pair of French military carrier pigeous.

T might be imagined that the present era of the eroplane and the wireless telegraph has no use for the swift and fulthful winged messengers which rendered such valuable service in the Franco-German and other wars. Many persons, indeed, are convinced

and other wars many persons, indeed, are convinced that carrier pigeons now serve only for the amusement of a few old fogy sportamen. These views are quite erroneous. The attention devoted to carrier pigeons by the governments of Europe, and especially by that of France, show that the ser not been forgotten, and that at least as

great a reliance is yet placed upon th as upon the mysterious and erratic Hertz-

At present France maintains twentyeight military pigeon houses, distributed among the fortifications, especially along the eastern frontier. These establish-ments, which are in charge of the en-gineer corps, are devoted to breeding and

training carrier pigeons
I have succeeded in obtaining special permission to visit the military pigeon houses of Vaugirard, near the fortifications of Peris, where the system of breed

the solution was explained to me by the commanding officer. The reader will be surprised to learn how much care is lavished upon the birds. The soldiers love the pretty little creatures, and follow their

educational progress with keen interest.

At Vaugirard, as elsewhere, the piges placed on the roof of a building, and each is divided into two compartments by an alley. The floor is com posed of plaster, covered with a layer of dry and moderately the sand, which protects the feet of the birds from fecal deflement. The water ressels are made small in order to minimize the quantity of water which the birds scatter in bothing, but whenever it is possible

to have a supply of running water on the roof of the pigeon house commedious busins are there installed, in which the birds can bathe freely and thus rid them selves of vermin

In all cases abundant ventilation is pro-vided, about 35 cubic feet of space being usually allotted to each pair of adult pig eons and 9 cubic feet to each young bird In order to facilitate the circulation of air, the roof of the pigeon house is never plastered, except in mountainous or other

The orientation of the house is a mat ter of importance. Nearly all of the French pigeon houses face approximately north-northeast, or in a direction opposite to most rainstorms. The administration takes care not to place pigeon houses near telegraph or telephone lines, which might injure blrds, stilking them in flight. Large trees and high buildings are also objectionable because they afford convenient perches for pigeons willing to shirk their flying exercises. The enges are inclosed in glass sashes in order to keep out rodents, and neighboring chimneys are covered with wire netting to prevent young pigeous from falling into them. All of the military pigeon houses are connected by telephone with the offices of the ngineer corps.

As a ruie, each pigeon house contains

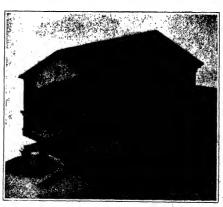

100 pigeons ready for mobilization. To maintain this effective force requires one or two compartments of 130 adult pigeons, a compartment of 200 young birds of the year, two detention pens (one for each sex), which are used only at a certain season, an infirmary facing the south, and a inboratory for the reproduction of

The denizens of a pigeon house are selected from lirds four or five weeks old, which have not hitherto left their natal house. They are first subjected to four or five days' observation in order to ascertain that they

The basket in which the pigeons are carri

are sound and to supervise their feeding. They are then encouraged to emerge from the house and fly s allowing them to escape voluntarily, without frighten ing them, so that they will recognize the entrance door. This is done about 3 P. M. daily. If the birds were driven out they would probably fly far and fail to return When adult birds are added to the colony the preliminary training must be greatly prolonged. The newcomers must first be penned up for a considerable time, then mated with older residents, and finally prevented from flying during the entire season by short-ening five or six principal feathers of the left wing

Type of dovecote used by the French Army for the senitary housing of its carrier piges

by about two inches. At the mouiting season the amputated feathers are replaced by whole ones. By this time the birds have become accustomed to their new The effective or mobile corps, which in May consists of 100 pigeons from 2 to 8 years old, is in-creased in October by the addition of 6 reserve birds and 23 young birds, 18 months old, which have taken part in two training campaigns. The winter colony, usually reduced to 130 birds by inevitable losses, produces 200 young for the next season's training.

The pigeons are fed on mixed beans, peas and vetches, which have been gathered a year. The individual daily ration consists of about 1% ounces of this mixture, divided into three meals, given at dawn, noon and S P. M. The pigeons are also provided with clay old morter, fine river sand, selt and egg shells or oyster shells, ground and

mixed in equal parts. This mixture, which is called "salted earth," is left permanently in the cages.

In pairing, care must be taken not to mate two birds of very light coloring, or of very close kinship or strong resemb-lance. Pigeons differing in color of piumage or eves should be mated, and cr ould be made between large and small,

old and young, shy and tame birds. After marital conold and young, say and tame birds. After marital con-cord has been established by a few days of enforced cohabitation in seclusion, the couple is allowed the liberty of the compartment. Two eggs are laid within liberty of the compartment. Two eggs are laid within a fortnight after mating and are hatched 17 days later. When the young pigeons are three or four weeks old and have begun to feed themselves they are separated from their parents and placed in a comp has a southern exposure and receives the maximum amount of sunlight. The young birds of the second or autumn brood are not usually preserved, because they are less robust and moult abnormally. The military training of carrier pigeous begins with

exercises in flying about the pircon hou Every bird is required to fly, during an hour at least, twice daily. These trial fights are supervised with great care. When the cages have been opened, the soldiers drive out the pigeons and prevent them from perching on the roof of the pigeon house. The few birds which set a dangerous example to their fellows by alighting on neighboring roofs are shot without computation. Well-trained pigcons have a range of flight which sionally carries them out of sight. Young birds begin with flights of a few minutes. duration, which is gradually increased to one hour at the age of three months. In order to make the birds understand what is required of them, the same signals are always given for the same evolutions. The pigeons are induced to leave the cages by shouts, clapping of hands and striking the partitions of the compari-ments, and they are recalled by whistling. after the mangers have been filled and

arrer the mangers have been filled and grain has been strewn on the floor. The fiying exercises are followed by training in carrying dispatches over geo-gressively increased distances. In ones of modification the places would be transferred to schee place which must be kept in communication with the army, in the event of transfer, it would seem

where on the testation is commented with this first his trive territories to be contained from a contact that and other senses of constrained are been limitatives. for a definite period.

The length of the course is increased from 20 kilometers (12½ miles) on the first day to 30 kilemeters on the third day, 50 on the sixth, 80 on the fourteenth, on the twentieth, 210 on the twenty-eath, and 300 on the thirty-fourth.

The yearling pigeons undergo nearly the same training, during six weeks. After a few preliminary releases in the After a few preiminary releases in the vicinity of the pigeon house, the young hirds attempt a flight of 10 kilometers, and the distance is gradually increased until it attains 200 kilometers at the end of the six weeks.

Practice flights are made over sea, as

well as over land, when the location of the pigeon house permits.

released early in the morning in order to avoid the heat of the day. In calm weather the normal speed of flight is 800 to 900 meters (about ½ mile) per minute, so that it is easy to calculate the time required to return to

The results of these practice flights are carefully recorded, together with losses of birds and other incidents.

As the purpose of these exercises is to train the pigeous for regular messenger service, the birds carry dispatches pre-pared specially for safe and easy transportation. The dispatches are either writ-ten or photographed. The former are writ-ten on sheets of very thin paper, measuring about 3 by 41/2 inches, which are triply folded and then rolled up, so that

triply folded and then rolled up, so that they form shender rolls about 1½ inches long, which taper slightly toward one end. The photographed dispatches are made from manuscript sheets measuring 11 by 44 inches, photographed on films measur-ing 1½ by 2 inches, which are simply rolled for transportation by the pigeous On receipt, the film is applied to a plate of glass and read with a magnifying glass

r projected on a screen by a lantern.

The practice dispatch contains a request that the capture of the pigeon be re-ported to the military authorities, and also bears the designation of the bird's home, the place, date and hour of release,

the number of birds set free, a serial number and some moteorological notes. The dispatches are carried in tubes of two sorts. One is a goose (uils 1, 4) inches long and 1/5 inch in diameter. The dis-

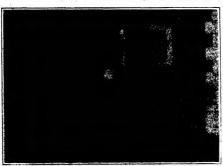

two sorts. One is a goose quill, 1/2, inches long and 1/6 inch in dismoter. The distance of the latcher esdess the pigeon with his left hard and process its breast to his own. Then he separates one of the median tail frathers and pusses it through the goose quill by compressing the borbs of the frather, which, when released, resume their normal position. The dispose that then introduced into the void which the shand of the frather leaves in the goose quill and is escured with a pointed match-click. In castless method, a take of absolution is attached to a single of the blief, and the disputable inclosed in a smaller take, it this incorrect places before certain margin by which it was sentily by incorping the properties of the pure, the comprehendance of the pure o

tich are revealed, furthermore, by a spiral band of col-ored celinicit borne on the right leg. A maie is indi-cated by 3½, a famale by 1½ spires or turns. There are seven celow: black, white, blue, red, yellow, green and violet, each of which corresponds to a different

In order to complete this brief sketch it is n to mention the material equipment employed in breed-ing and training the carrier pigeons of the French army. This includes the equipment for the transpor-tation of pigeons, in addition to the equipment of the

As the pigeons are allowed to leave the house at fixed hours only, it is necessary to place, at the entrance of each compartment, special entrance cages, which are set in the windows. These cages are so constructed

A mule laden with carrier pigeons.

Cart for transporting carrier pigeons.

that the birds can enter f vely but cannot escape. The eage is issually 28 inches high, 32 inches long and 28 inches deap. The sides are formed of from wires about 1½ inches apart, and the top is covered with a wire 114 inches agart, and the top is covered with a wire grating, having messles measuring 4 by 5 inches, an interval sufficient for extrance, but too small for exti. The upper helf of the front is like the dides, but the lower half is closed, by a morable frame of inverted U-shahed wires, which water on hinges from the top her of the frame, the betton bar of which allows the lower ends of the whist it, more inward, but not outward. The returning piacesis, slighting on the board in fract of the claim, enter by pushing these swinging wires foward, but come, but come by the same way. The morable frame is raised by a cord to release the piaces. See allegating the and is not one specuous in order to assist, young birds in finding their

way home. The breeding nests are arranged in superposed cells, each of which contains two nests, for the second clutch of eggs is often laid in less than three weeks after the first broad is hatched, and before the young birds are able to feed themselves. The top of the group of cells forms a promenade for the pigeons. The cells are closed, in front, by light wooden gratings, which are easily removed when the nests are cleaned.

The drinking fountains are of the familiar siphon type, and are composed of three-gutton bottles, sup-ported in an inverted position on iron tripods over shatlow troughs, into which their mouths dip. The house equipment comprises various appliances, which would st none except pigeon fanciers.

The pigeous are conveyed from place to place in that

rate pigeons are conveyed from piace to make in mar wicker cages. The birds are released for flight by opening a small trap door in the top of the cage. These enges are made in three sizes, which accommodate 25 to 30, 12 to t5, and 4 to 6 pigeous, respectively. The smatlest, or truining cages, are covered with muslin. The cages are transported by railway, in wagons or on mule-back,

The French military authorities encour age the breeding of carrier jugeous as far as possible. French civilians maintain numerous pigeon houses, which are under the supervision of the war ministry, and in which thousands of carrier pigeons are trained. The inhabitants of the départment du Nord, like their Belgian neighbors, are enthusiastic breeders of carrier pigeons. The training begins with the ad vent of warm weather, and atmost daily hundreds and thousands of pigcons are sent out, at first to neighboring departments, but later to the center and south of France, where they are released. The officint military recognition of the carrier officint initiary recognition of the carrier pigeon dates from the Franca German war of 1870-1871. Although the birds then employed were poorly trained, they necomplished such remarkable feats that their aid in future wars is refled on with confidence. It is probable that pigeons will soon be carried by acrophues, despite the instinctive reluctance of aviators, who regard the birds as dangerous pas sengers. The rigging of a swiftly moving aeroulane might, indeed, be seriously in jured by the impact of a pigeon, and the fouling of the propelter by a bird might be still more disastrous. For the purpose of averting these accidents at the moment of release it has been proposed to drop the pigeon, head downward, through a long vertical tube, so that the acceptane would be far away before the surprised tird could right itself and begin its flight This device will be tested by experiment during the conduct senson.

#### Coffee from Dried Figs

EVER since coffee has been a popular beverage, apparently, efforts have been made to find substitutes for it, either as mere adulterants, like chicory, or for the sake of greater wholesomeness or cheapness. Rye and other grains, lupine. acorus, beets and carrots have all been thus used, but the tig coffee, or Feigen Kuffer, which has latterly come into asc in Austria and elsewhere, is a decided novelty. Les Annales quotes M. Trabut of Algiers as saving that an excellent coffee can be made from dited and roast ed figs, which need not be of the first

They are dried in the sun or in even orating pans, according to estimate, and then rousted in ovens (11) brown or almost black and quite brittle. They are then ground up and the resultant powder is pressed

then ground up and the resumant powher is pressed tho tablets. These must be kept di. When made use of they are merely dissolved in hot weter. One hundred kilos of the dry figs give 75 kilos of the dry powder. The figs cost 15 francs and the powthe dry powder The first cost 15 frames and the powder sells for 60 frames whotesaile and 100 or more at retail, so that the trade ought to be prolitable if a demand can be created. The beverage is said to be agreeable in color and flavor with a somewhat sweeter taste than that made from chicory

### A Soft Laboratory Wax

A FAMOUS laboratory wax used us a fitter or for Auttaching light articles to glass, etc., is made as follows: Beeswax, 40 parts: Venetian turpentine, 10 parts; rosin, 1 part; color with vermition Melt the ex and rosin, add turnentine and cotor. Stir until cold

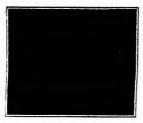

#### Curious Resemblances in Nature

#### By Harold Bastin

TO truce in matural objects a resemblance, either struc-tural or pictorial, to other ob-jects with which they have no real connection is a diverting pastime. Moreover, though at first thought It may seem some-what puerile, it can to fact be turned to good account as a means of stimulating the imaginution, and inducing the mind to embark upon a course of iruly schoolike Investigation which may lead to Important discover This applies in particular to the training of the youthful student. All those who have guined experience as teachers will readily admit the laitled dif denity which exists in arousing the intelligent interest of a class in the subject of study. In other words, something is needed to set the unchinery of the mind in motion. For example, a flower or an insect, as such, any fall to evoke the desired response. But If we can point out some curious or grotesque likeness which it bears to a familiar creature or thing, we are able from this starting point to lead on by carefully planned stages to such great questions as structure, natural affinity, and adap

Take, for instance, the case of the orchids. Several species bear popular names which suggest the likeness of the flower to some member of the unimal kingdom Thus, we have the man orchid, e orchid, the spider orchid, the lizard orchid, and the monkey orchid. It is true that some of these supposed likenesses are highly imaginative, but others are wonderfully distinct, and will bear close scrittiny. The bee orchid (Ophrys apifera), for instance, is very much like a small highly colored humble-bee, the wings, head, untenne, and hair, body being all reproduced in case of the so-called mun orelid (Accres anthropophora) the general effect of the flower is very quaint and striking, looking a series of small green pup In the very curious fly orchids (Ophrys mucifera) the likeness to an insect is not marked, although a vivid imag ination can conjure up wings, an iennæ and a protruding head, but the lower part of the flower resembles most closely a little doil, or monkey, dressed in a sleeping sult with a white sush round its waist

In all these Instances the resemblance is mainly due to the shape of the lip or bebellum of the bloom. Now orchids rank admittedly among the most high ly specialized flowers, while their extraordingry modifications are the result largely if not entirely, of insect interference. Many of those flowers depend entirely up-on the visits of insects for politic ation, and without the aid of winged emissaries Cupid they are quite unable to set seed. The labellum is the recognized allighting platform upon which the losset stands while it probes the recesses of the flower in search of nectar, and us orchids are so closely ussociated with insects, we must assume that the special shape of the labellum in each instance is more or less definitely related to the convenience of the guests that are specially catered for by

Most young people are familiar with the canary-hird flower or the common causey cre (Tropacolum canaricase), here again we find that the nuusual form of the blossom is due to insect visits. The blooms of this group of plants seem cially designed to meet the n chally designed to meet the needals, which seldom or never settle on the flower, but hover in front of it; tightly poted on their amplity-moving wings. While in this position the tongue is unrolled and thrust far back into the "spur" of the flower where the nector is stored. Meanwhile. the head or body of the moth comes into contact win the pin-til or stamens, and pollen is de-posited or removed, as the case may be. The flowers of Tro-pasolum are among the few in which nectar is secreted by the calyx, which is brightly colored and extended to form a long spur. The lower narrowed part is the nectary, and the award liquid is sometimes so abundant that it wells up to the moth. This spur, of course, forms the head and neck of the little canary bird, while the flamboyant ary bird, while the flamboyant tail is represented by two of the petals. When still a bud, the flower also presents a subdued, bird-like aspect.
An interesting re

a swan is presented by the unopened flower-buds of the huge tropical birthwort Aristolochia This and allied species may often be seen growing in hothouses, and may be compared with the species of temperate regions, such as Aristolochia tomentosa, and A. sipko—the well known "Dutchman's pipe." All these very remarkable flowers, which rival the orchids in the grotesqueness of their form, are designed to attract and imprison small Dipterons (two-winged) flies which feed by prefence upon filth and carrion— hence their foul smells and lurid colors which seem to suggest putrescence. The structure of the flower varies in different species, but the essential points are (1) an alluring area leading to (2) a throat or vestibule which, in its turn, conducts to (3) an inner chamber or prison. The swan-likeness of the flowerbud in A. pigas enables us read-ily to appreciate this description The body of the "swan" eventu ally expands to form the alluring area-an enormous expanse. alty-six inches long by eleven inches broad, the whole surface of which is covered with a net-work of blood-purple veins. work of blood-purple veins.

These converge about the entrance to the month or vestibule
(i.e., the neck of the "swan"), which is lined with inward-pointing hairs. Flies which settle up the alluring area are indu by the strong scent of the blosby the strong scent of the blos-som to enter the vestibule, which freely admits, and even facili-tates, their entrance. But if they attempt to reture, they are prevented by the hairs. Thus they are doubt to penetrate the stage are doubt or penetrate the stage of the flower

#### Clock That Speaks the These of Day By W. R. L.

(The clock and the two dry cells necessary to operate may be placed inside the record cabinet.) When wishing to play records simply remove the rack 7. By substituting a piece with one or the end the phonograph stops automatically at the end of each record.

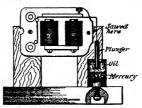

#### A Mercury Interruptor By George F. Worts

IN SO FAR as theory is concerned, interrupting the current for a spark coil for wireless use is a simple matter. In actual practice, however, contingencies arise and interruptors occasionally manifest contrary tend ich cause their application in wirele raphy to be a source of no little appoya

For instance, the text books tell us that in an electrolytic interruptor small non-conducting bubbles form and break on the anode with mechanical regularity. thereby causing an interrupted current flow. How a ple it sounds! But somehow or other the bubbles fail to form and break regularly and, taken with the rapid heating properties of an interruptor of the electrolytic type, generally cause it to be a rather unsatisfactory of apparatus.

In the case of a water cooled, platinum electrods electrolytic interruptor, the above difficulties are usually not present, but the prohibitive cost of this instrument bars it from the majority of amateur stations.

As a parallel case to the above, we find the spark

Mercury interruptor made out of an electric bell.

coil vibrator, unless of expensive make, to be generally

nsatisfactory and inefficient
A form of interruptor which has met with a great deal of approval among the advanced class of experi-menters, is the mercury independent type. Singularly mgh, this unique and efficient form of current breaker, which is employed extensively in electrical work account of its positive operation, has been neglected almost entirely by the amateur wireless experimenter, usually so prompt in adopting a new idea, provided stified in doing so

e is justified in doing so.

We will attempt in this article to acquaint the experimenter with a simple and cheap, though efficient, form of the mercury interruptor for wireless use

From an ordinary electric house bell saw off the jut-ting arm which supports the bell. Remove the round clapper from the end of the vibrator and solder a 1/6inch round brass rod about 2 inches long in its place. Bend the extended part of the vibrator at right angles insua in extenses part of the violator at right angles to its usual position and parallel to the magnets and mount the bell base to square wood standards erected to a wood or rubber base having the dimensions of % by 8 by 6 inches.

ne magnets are now actuated, the brass red will

vibrate up and down with about a \( \frac{1}{2}\)-line stroke.

A small brass cup, 1 facth deep and \( \frac{1}{2}\) facth wide, should now be procured and a hole tapied into the bottom to accommodate an 8/32 thread. A machine screw passing up through a counter-sunk hole in t screw passing up through a counter-sunk hole in the base, located directly under the brass plunger, will secure it firmly. By bending the extended portion of the armature, the plunger should be adjusted so that fix lower end it. §§ inch below the level of the top of the cap. The caps should then be filled with mercury to a level % inch below the end of the plunger. A good grade of light cylinder oil should then be poured roury until it is about level with the top of

the cup. This will quench any arc that might possibly form and, incidentally, will prevent the mercury from splashing out.

In operation, several dry cells are required to actuate the magnetic. The vibrator of the spark coll should be screwed down tight, the battery circuit switched on and the contact screw of the completed interruptor adjusted until the desired spark frequency is obtained. A little practice in this direction will accomplish the

The mercury interruptor above described requires little or no attention and is practically non-heating.

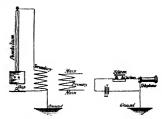

If used on the regular lighting current, either afternating or direct, a water rheostat should be provided, as the resistance of this interruptor, unlike the electrolytic, is very low and 110 volts would prove too strong for both itself and the spark coll

#### A Seconds Pendulum By C. C. Kiplinger

A SECONDS pendulum is frequently used in the physics laboratory. After an extended experience with unsatisfactory contact pendulums of the mercurial type, the following instrument was devised which has ed itself successful in practical use The details of the contrivance are shown in the sketch

A wooden rod (a meter stick does nicely) has a screw eye attached at one end. This is filed to a kuife edge, so as to form a frictionless point of support. The fixed kulfe edge is made from a small file, also brought to a sharp edge by means of a second file. Two plates of thick sheet lead and two short bolts comprise the bob of the pendulum. A short length of wire fastened to one of the plates and lying in the axis of the rod, serves for one terminal of a small spark gap. The othe terminal may be either a small metallic ball or rad with The other rounded ends

The connections should be made with a trans or induction coll and the ground, as shown in the figure A short gap should be used and the spark should be but little longer than the gap in order to moure a vertical spark With the apparatus in working order, every

onds pendulum as a wireless transmitter.

swing of the pendulum gives rise to a spark, which in turn semis out electro-magnetic disturbances into space

The instruments used for the detection of these disturbances are, a 75 ohm telephone receiver, a modified Massle's oscillaphone, and two dry cells, connected as shown in the sketch. The oscillaphone comprises two carbon knife edges insulated from each other and about 3/16 of an inch apart A piece of stiteon is laid acre solve of an inequality and precess standardons had across the edges. A piece of galeon or a light sewing needle may also be used. Under the conditions in which we work, silleon has proved far more sensitive. The allicon should be moved to and fro on the carbon supports untii the signals are loudest

Any desired number of detectors may be operated by the "master pendulum," and these may be in differ-ent rooms, or in an adjacent building. Such a pendulum will be found far superior to the ordinary type.

The Department of Terrestrial Magnetism of the Carregie Institution, the all-important center of world-wide magnetic surveys, is at last to have its own offices and laboratories in Washington, after having been domiciled in an apartment house ever since it was founded. of about seven acres has been purchased in the same suburban district of the capital which includes the Bureau of Standards and the Carnegie Geophysical Laboratory, and the new buildings are expected to be ready for occu-pancy early next year. The magnetic survey yacht pancy early next year. The magnetic survey yac "Carnege," attached to this institution, early this ye crossed the South Atlantic from the Falkland Islands. St. Helena, and then returned to the South American side. e is due in the United States at the end of the after three years of circumnavigating the globe. Dr. L. A. Bauer, director of the department, is to deliver the Halley lecture on "Terrestrial Magnetism" at the University of Oxford, May 22nd. 1914.

#### Recent Improvements in the Reciprocating Engine Art

In is generally conceded that the reciprocating engine has reached a very high stage of development, that there can be no radical departure from the universally accepted engine construction without serious loss in

The direction of improvement, and, indeed, the proper direction, has been in working between the widest attainable limits of temperature

Meam must enter the machine at the highest possible temperature, must be protected from waste and must retain, in the moment before exhaust, the least possible amount of heat. Among the investors who have recently been working along this line is Prof. Johann Stumpf of Berlin, whose engine is of the type known as the "ind-directional flow" steam engine, In such engines, as distinguished from "counter flow" engines, the steam once admitted into the cylinder dose not return in its path. The steam is permitted to enter each end of the cylinder alternately and exhausts through a set of ports which entried the middle of the cylinder, these exhaust ports being controlled by the histon at the end of its stroke

In the fature, the steam, nested of helius introduced into the egithed effect, enters it from the holius head. At through the higher B, thus providing a live steam jacket we thank the steam is neither cooled on room the steam of the steam

A jet condensor E is placed in a box  $D^*$  of the exhaust pipe  $D^*$  in order to cool the exhaust additionally to facilitate the sweeping out of the exhaust steam

to maintain the sweeping out of the exhaust steam. This construction provides a hot inlet and a cool exhaust, and there is a gradual full in temperature from the inlet to the exhaust, the working steam at the end of expansion being arranged in layers of decreasing dyness.

An enormous drop in temperature of the steam takes place during the expansion and exhaust of the steam, and the heat, therefore, passes rapidly from the hot jacket to that layer of steam adjacent thereto. The heat thus flowing toward the exhaust belt is to a great extract absorbed by the working steam and is trapped by the platon at the commencement of the compression stroke, instead of being sweep out out of the exhaust, so that this heat, transferred to the steam, is again transmitted to the end of the cylinder by the pumping action of the platon. The heat given up by the cylinder head to the steam in the cylinder is retained within the latter, since this steam is itself retained therein, so that the head presents the peculiar phonomenon of a heating jucket with no loss

in actual tests it has been found, when employing superheated steam, that the temperature of the cylinder wall at the inlet is higher than the temperature of

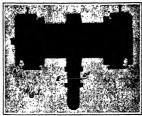

Fig. 1.—Uni-directional flow condensing engine

Figs. 2-3.—Forms of uni-directional flow engine

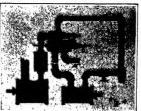

Fig. 4.—Controlling gear in place.

the stam in the jacket. In unddispetional repeats with since the points at which release and compresses begin are never varied, so that, in an emisse grayerly designed for its normal load, the compression is excessive when the engine is starting or remains at high loads.

Prof. Stumpt has recently patented a device whereby the excessive compression may be relieved. This device consists of an auxiliary exhaust valve which is connected to the cylinder and operates automatically. This valve may be cut out when not required, without interfering with the economic working of the engine during normal running.

The figures show two variations of this investion. In Fig. 2, the cylinder A, in which the piston moves, has auxiliary exhaust passages leading from the failers, which passages have pipes leading to a valve chamber is which there is located a steam operated valve, shown at F. The valve casing B is connected to the live steam inlet by means of a pipe D manually controlled by the

The entering steam, the valves  $O^*$  being open, passes into the cylinder and also through the pipe D into the casing B, and the valve P moves to the opposite end of the casing, movering the port C. The steam may then not only exhaust through the main exhaust ports controlled by the piston, but isno through the passage O to the casing B and port H. This exhaust continues until the compression pressure on the one side of the piston is greater than on the other, the auxiliary ath-aust continuing for a conditorable part of the stroke, whereby only a low compression is attained, such as is unfifted in to meet the requirements during starting or at high loads.

In Fig. 3, the plipe C is condited and the value T is actuated by the auxiliary enhance pressure through the plipe R controlled by the value S instend of the live steam as in Fig. 2. The operation of the derive shown in Fig. 3 is precisely the same as in Fig. 2, except that the exhaust steam operates the value T instead of the live steam. The values S are operated simultaneously by the rod S and the value T is of different construction.

By closing the vaives  $D^1$ ,  $C^1$  and B, when not required, the economic operation of the engine during normal running is not interfered with.

In the operation of blast furnaces it is necessary frequently to slow down one or both engines, and often it is destrable to run the high pressure engine alone or the low pressure engine atone or the low pressure engine atone, using boiler steam. This result is ordinarily secured by placing throttle and stop valves in the piping between the high and low pressure rendence and providing a separate throttle and a pressure reducing valve for admitting boiler steam at reduced pressure to the low pressure cylinder. A safety valve is placed on the receiver, or on the pipe between the high and low pressure cylinders, to allow the high pressure cylinder to exhaust outboard in case the receiver pressure builds up too high. These valves are all separate, and all except the safety and

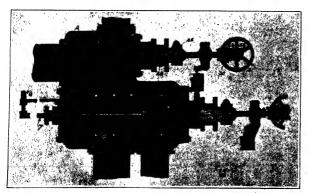

Fig. 5,-Detail of controlling goar shown in connection with cylinders and holler in Fig. 4.

San Sanda

Fig. 6.—Reciprocating classents and valve

they allow his manually operated, agents manipulsand and with the tr-in augment. Her produce the dustine is with that rescens, but it is clear the property or disting of the right is in eveny expanse or opening or if the wrong valves in right ing the errong waters in right sense, may cause one or both of the tries to stop. Constitut of the blast on would follow stoppage of both eawhich would reliev stoppage of both en-gines is a sections matter in blant furners operation, one of the consequent dangers being serious explosions of gases that work back into the blowing tube from the

forms all the functions of the above-tioned valves, many of them automa ally, renders it impossible to start of mible to start or to stop both engines by the manipulation of a single valve, and makes it impossible for ntal stoppage of one engine to our the stoppage of the other, has recently been patented by F. E. Norton of Younge

The Norton controlling gear, which is shown in Figs. 4 and 5, employs a casing A (Fig. 6) with partitions B, C and D, located between the high and low presre cylinders. Two cylindrical shells S sure cylinders. Two cylindrical shells 3 and 20 are placed in the casing A, thus providing two valve chambers in which the valves 5, 6, 16 and 24 are placed. The annular chamber 1 formed by the partitions is connected by a pipe to the exhaust of the high pressure cylinder and communicates with the valve chamber 4 through the ports 2. The valve rod 7 is manually adjustable by the lever 8 so as to cover or to uncover the ports 9 and 10. valves are so posited on the rod 7 that the ports 2 are never covered by th valves 5 or 6 within the limits of their varies 5 or 6 within the limits of their travel; that both ports 9 and 10 are closed in their mid-position; and that ports 9 are closed when ports 10 are open, and

The ports 9 lead to the chamber 12 communicating through the pipe 13 to the receiver 13c. (See Fig. 4.) The ports 10 lead to the annular chamber 14, communicating through the auxiliary exhaust conmeetion 15 to the condenser or atmosphere. The ports 11 are normally closed by the spring operated valve 16, the latter being forced to opening position against the ree of the spring 17 by excess of pres mre in the chamber 4

offer steam is introduced by the pipe 18 into the chamber 19 and thence into is into the chamber is and thence into the valve cylinder through the ports 22. The valve 24 is normally held is open posi-tion by the spring 25, permitting the steam to pass through the ports 23 into the nber 12, but capable of being forced to the right to a closing position by pres to use right to a closing position by pressure in the chamber 12 acting on the plunger 28. The pressure on the chamber 12 may be varied by changing the compression of the spring 25. This is accomplished in the same manner and by the plished in the same manner and by the same mechanism used in changing the compression of the spring 17. The rota-tion of the nut 30 by the hand wheel 31 through the gears 32 and 33 causes the through the gears 32 and 33 causes the rod 35 to vary the stness on the spring 32 at the opening position of the valve 24. It will these bo obvious that the valve 24 serves both as an adjustable pressure re-ducing valve and as a positively controlled throttle valve. Sudden movements of this valve are checked by the dash pot, showe and link arrangement, thereby securing a smoother action.

e operation of the device is as fol-The operation of the device is as fai-lows: Assuming that the valves 5 and 6 are to the right, giving free exhaust through ports 10 and closing ports 9, the low peasure eagine would use the intar-cel by maintenance are so the pro-mitted of the control of the control of the third vision of the control of the con-trol and run the low pressure engine on

he sists; ports 9 and 11, closed; ports 10, open; ports 26, partially and variably open, and maintaining approximately con-stant pressure in chamber 12.

This manipulation of the parts runs the eine "eimple"

To compound the engines, the spring 17 to compound the sengines, the spring it is adjusted to a pressure very slightly higher than the desired receiver pressure, an adjustment seldom requiring attention; then the spring 25 is set so that valve 24 will open at a pressure very slightly below desired receiver pressure; lastly, valves 5 and 6 are moved to their extreme left position by means of handle 8 acting or rod 7. The engines will now operate

Conditions now are: Ports 9, open; ports 10, closed; ports 22, closed, but ready to epen if pressure in chamber 12 falls; ports 11, closed, but ready to open

f pressure in chamber 4 rises.

If the high pressure engine be now accially stopped, valve 24 will open and supply steam to the low pressure engine that it will continue to run. If the low pressure engine be accidentally stopped, valve 16 will open ports 11 and allow the high pressure engine to exhaust in the pipe 15 so that it will continue to Normal method of stopping either engine: First convert to single expan sion operation by moving valves 5 and 6 to the right; then to stop high pressure pressure engine alone, draw valve 24 to closed position by the action of wheel 31.

This construction affords ease of manipulation and freedom from accidents stoppage, the evil effects of which have been explained.

In wool combing machines a rapid re ciprocatory motion without undue vibra tion is required to operate the brush or dabber which drives the wool fibers into the spaces between the projecting needles Most machines now used, even with care fully constructed, oppositely m ance weights, positively operated, are sub-ject to a residual tremor which is very disadvantageous.

A patent recently granted to Boys a Pierney shows a reciprocating engine fo producing such a rapid reciprocatory mo-tion to operate the brush or dabber of s wool combing machine

In Fig. 6, the hollow piston r tached to the brush of a wool combing tached to the brund of a wool comming machine, or to a mold box, or to any other device required to be reciprocated rapidly where little external work is required. The piston with its heads M and N comprises the working element of the machine and the cylinder C in which the piston op erates is attached to the wool comb chine frame by means of the springs 1

Tive sir or steam is admitted to the

port Q and the space between the head the platon is filled with the motive fluid which acting on the larger head M lifts the niston until the grooves R are un covered. The air then passes through these grooves and through the small pas sage 2 to the upper side of the valv forcing the valve upward against its spring T and closing the exhaust passage W from the space above the piston. Part of the air also passes to the space above the piston, where it is compre the piston, where it is compressed and acts as an air buffer or elastic finid spring. The pressure in this space now becomes equal to that in the space between the two heates of the piston and greater than that in the space 3 below the head N, and the whole piston is driven down-ward, compressing the air in that space. The exhaust valve S re mains closed the presure in the space above the piston falls in consequence of expansion to such an extent that the spring T overcomes the air pressure on the lower side of the valva,

squent pressure arising in the groover and passage 2.

The period of the stroke at which the

exhaust valve opens and closes is regu-lated by the screw. The passages O and P are provided to allow air to exhaus from or to enter the space 3 near the enof the stroke and so prevent creeping of the piston in the cylinder and ultimate ere of its motion

It will be observed that the trapped air elow as well as above the piston, by its empression, is most effective in returning the piston quickly, and this is one of the advantages of this method of effecting the reciprocation for extreme rapidity ove the method of eccentric driving now com monly used

#### Notes for Inventors

A Doll With Different Faces .- Chest Lombra of Meriden, Conn., has secured patent, No. 1,059,178, for a doll which has a fixed face and an extra face or faces hinged at the lower edge of the fixed face so that they can be turned down against the body of the doll or up over the exposed face, a bandeau being provided to hold the upper edge of the movable face when the latter is adjusted to position for use.

An India Rubber Substitute,--- A proce of producing an India rubber substitute is described in the patent, No. 1,061,881, to n of Crefeld, Gern In this process geletin is mixed with gly-cerine and with camphor, the latter being dissolved in acctone and the mass is treated with sulphur.

Artificial Signal Clouds Kübel of Washington, D. C., has patented a method of signaling, No. 1,062,782, in which cloud-like bodies are formed by chemical reaction and their discharge is controlled in accordance with the signal desired to be given. In discharging the cloud-like bodies, fluid pressure is utilized.

A Cranberry Dryer. - A patent. No 1,032,969, has been issued to Henry H. Harrison of Boston, Mass., for a dried entire cranberry having a vented skin and for the process of drying fruit in which the inthe proc terior of the fruit is vented through the outside thereof while retaining the integrity of the fruit; the vented fruit is afterward subjected to the action of a drying agent.

A Process for Tempering Copper.-William H. White of Hazleton, Pennsylvania, Hazleton, and one third to Jacob M. and Margaret Schappert of Dorranceton, Pa., has patented, No. 1,062,067, a process of tempering copper wherein the copper is heated to a high temperature and is imnersed in a hardening bath containing lime water from which it is removed as soon as it blows and is then placed upon a hard surface and struck with another hard surface.

A Way to Prevent and Cure Premature Baldness.—A patent, No. 1,062,025, to Bernard H. Nichols of Ravenna, O., shows a hat band having corrugations on its side which form protrusions and depressions which form protrainons and depressions, the purpose of the construction being to avoid interference with the free circulation of the blond to the soalp whereby the pat-entee claims to prevent and cure premature haldness

Electrical Rat Trap.-Henry Carter of Pittsburgh, Pa., as assignee of one half, has received with Raymond H. Pryor of same place, patent No. 1,052.957 for a rat trap in which there is a platform, an elecouting circuit and a motor circuit con trouled by the movements of the platform, the motor circuit acting to operate a clear-ing mechanism by which the rat will be thrown away from the trap after it has been by stepping on the platform

the head wheel SI antif open enough to attract and run when the valve opens and ext the valve state and run is head of the particular and the part

the controlling means including a plurality of contacts connected in multiple with the field winding of the kinematograph motor.

Improved Flexible Tubing .-- In patent No. 1,053,394, to Henry Hubbell of Ash-burnham, Mass., assigner to N. T. R. Al-mond Manufacturing Company, same place, is shown a flexible tubing which has an inner coil and an outer coil which is located n the convolutions of the inner with the inner surfaces of the convolutions of the outer coal given an ogee shape in cross section and engaging with the inner coal along a relatively narrow line in the normal position of the tubing.

Bill Nye's Prophetic Vision .-- Many years ago, before the days of the phonograph, Bill Nye wrote a humorous suggestion that an automatic machine be used for the delivery of political speeches from car platforms. Bill Nye httle suspected how soon talking machines would be reel-ing off political speeches all over this land of ours. They were used in the last presi-dential as well as in the one four years before. When skillfully employed they avoided "repetition or the wrongful application of local gags" which Bill Nye claimed as a great advantage of his pro-posed political machine

A Novel Photographic Process. ent whose purpose is to provide for photographing an object with any desired background has been issued, No. 1,053,887, Offigo Sonitag, of Erfurt, Germany. This patent includes a translucent serven slightly tinted with a non-actime color or a color having a weak actinic action. This screen is located behind the object and the face side of the object is lighted and the sensi-tized plate or film is subjected to a single exposure to simultaneously impress therein the images of the object and the projecting background, the background being pro jected upon the translucent screen from the opposite side thereof to that occupied by object to be photographed.

First Superintendent of Patent Office .--There hangs in the office of the Commisor of Patents at Washington a portrait of Dr Wm Thornton, the first superintendent of the Patent Office. The picture was painted by Gilbert Stuart whose porof George Washington are justly rated. The portrait was presented to clebrated. the Patent Office in 1871 by a mere of Dr. Thornton, Mrs. Talbot, widow of Hon. Isham Talbot, U. S. Senator from Kentucky. Dr Thornton was an intimate friend of President Washington, who, in 1794 appointed him one of three commissioners to survey and lay out the Federal capital. The Patent Office for most of the Doctor's administration was not very extensive, as we are told it consisted in 1816 of three persons: Dr. William Thornton, clerk, at \$500, and Benjamin Fenwick, messenger, at \$72

Three Wardrobe Trunk Patents. popularity of so-called wardrobe trunks is manifested in three patents, Nos. 1,051,-936, 1,051,937 and 1,051,938, issued to George H. Wheary of Raeme, Wis. The patent, No. 1,051,936, includes a novel construction of folding wardrobe section made of which legs are pivoted and adapted to be swung into position to support the wardrobe section when the is adjusted out of the trunk body and raised to an upright position. The patent, No. 1,051,937, provides a folding rack in connection with a swinging door, the rack being arranged to engage the door whe latter is partially closed in such manner as to foreibly close and lock the door in posi-tion when the rack is folded out of position for use. The third patent, No. 1,051,938, has the trunk body provided with an end wall which is mounted to swing outward and rest flat down upon the floor, and the wardrobe section includes a rectangular tray, one end of which is provided means co-operating with means on the swinging end wall of the trunk body whereby the tray may be secured to the said end wall when the said wardrob is adjusted to upright position for use as a

## The Ten Greatest **Inventions of Our Time**

We hear much of the great inventions of the pastthe telegraph, the sewing machine, the telephone, the reaping machine, photography, Bessemer and open hearth steel, the steam engine and the phonograph. Yet the inventions of our own time are as epoch-making and as dramatic as these.

Perhaps because we have become accustomed to the use of the old machines and discoveries, perhaps because the achievements of latter-day inventors succeed one another so rapidly that we are not given much time to marvel at any one of them, we have not fully realized how stirring and wonderful are the products of modern

Only five years ago the man-carrying aeroplane made its first public flights; only the other day hundreds of passengers on a sinking ship were saved with the aid of wireless telegraphy. At least a dozen inventions as great have been perfected in our own time, and all of them have made a man's work count for more than it ever did before, and have made the world more livable than it ever was.

Why should we not tell the story of our own deeds? Why should we not review the industries created by men who are still living, men whose names will go down into history with those of Watt, Morse, McCormick and Howel

That was the underlying idea of the November Magazine Number of the Scientific American. We knew that the "ten greatest inventions of our time" was a big subject when first we planned the number, but how big it was we never realized until we surveyed the field of modern invention.

Then we saw how astonishing was the progress made in our own day, how much mankind had benefited by the inventions of great modern intellects. We began to appraise inventions, to weigh one against the other, and to determine in our own minds which ten had contributed most to human progress and happiness, which were really great pioneer inventions, and which merely remarkable and valuable improvements on successful past conceptions. There were so many achievements to consider that it was hard to arrive at a definite conclusion.

The upshot of our own thinking has been to leave to our readers the decision

### What Are the Ten Greatest Inventions of Our Time. and Why?

For the Three best articles on the subject, we offer in the order of merit, three cash prizes:

Curious Resemblances in Nature

(Concluded from page 34.) nted by the head of the "swan") where they are brought into contact with ential, or sexual, organs. In this chamber the flies are held captive. Those which have come from other blooms bring pollen with them, and thus effect the pollination of the pistil. Then, when the stamens attain maturity, the whole company of imprisoned insects get dusted anew with polien; and not until the flower fades, and the hairs in its throat

Perhaps the most striking of all floral esemblances is that presented by the resemblances is that presented by the staminal column (the petals having been removed) of the Brazilian milkwort known as Schubertia (or Araujia) grandi-flora. The likeness is that of a benevo-lent looking old gentleman, every feature peing most perfectly portrayed; while, as rotated from right to left between the fingers, the visage appears three times in succession—the right eye of one face be coming the left eye of the next, and so course this remarkable apparition is merely coincidental to the structure and roloring of the parts concerned. It has no direct bearing upon the adjustmen of the flower to its environm theless, it calls our attention to the union arrangement of the essential organs which characterizes the natural order Asclepiaduceae. As in the case of the orchids pollen is combined to form man which are torn away bodily by an insect of appropriate size and carried to another bloom. In the case of the Schubertia, the insect, coming to the flower for the nectar which it secretes, pitches upon the staminal column, and sooner or later gets its that column, and sooner of later gots are feet into the long, gaping slits—one of which is seen to each aide of the mock face. As the insect attempts to escape, its feet are guided upward, and become wedged in a narrow notch in the black disks or "clips" (the "eyes" of the face), the disks, together with the pair of poller masses attached to each. When large and powerful insects are involved, the device works to perfection; but small insects are able to effect their escape, and are held captive by the flower until they die-a contretemps which defeats the object (i. e., cross-pollination) for which ate contrivance exists. On this account these flowers are often spoken of as "cruel flowers" or "pinch-trap flowers." But when a powerful insect drags away a pair of pollen-masses, the latter undergo a remarkable twisting movement, by means of which they are brought close together. This facilitates their insertion into the stigmatic chamber of the next bloom which is visited by the insect. In the vicinity of these flowers one may often capture large wasps and other insects with large numbers of pol-len-masses, or the clips from which the

florescence, of the sweet sedge (Acorus calamus) deserves mention because of its striking resemblance to a round file. The plant belongs to the order Orontiaceae (allied to the Arums), and is a native of Eastern Asia, although it has at Eastern Asia, although it has spread to other countries, and is conserved in South-ern Russis, whence the rhizomes are ex-ported. They yield an aromatic stimulant and tonic bitter, which is employed medicinally and for flavoring beverages. sence is a spike of small, closely crowded hermaphrodite blossoms which open in rotation from below upward. Selfpollination, or autogamy, is out of the polimation, or autogamy, is out of the question, because the stigmas of the indi-vidual flower fade before its anthers open. It is true that the stigmas of flowers in the upper part of the spike become recepwithout the assistance of insects. Kerner that in Purcey, where the plant is not indigenous, it is always startle. But further saw, where the plant is not indigenous, it is always startle. But further saw, where the startle. But further saw, where its deep plant is not indigenous, it is always startle. But further saw, where the same plant is not indigenous, it is always startle. But further saw, where its deep plant is the given in the case of the given in th

need Jawa of the

oury aptly company "strong box to which has the key;" for it is a smaller bees rarely set long-tongued bee to bring about its pollination. It is, indeed, a ki nel, into which the insect visitor crawl to reach the nectar which is ed at its extremity. At the entre this tunnel, press the pollen-covered anthers, and an exam inution of the flower shows that an and other insects, could they gain access would crawl down to plifer the hom-without touching the anthers at all. large bee, on the other hand, file up the the pollen with its hairy back. facts explain the tightly-closeed the snapdragon bloom, which call for a large, robust insect to force them apart.

Perhaps the most curious part of the ragon, however, is its irregular seed capsule. The accompanying photograph might pardonably be mistaken for a collection of skulls in some muse section of skulls in some museum. Tet it really represents a few snapdragon pods mounted on pin-points. The three holes which seem to represent the eyes and mouth are, of course, the orifices through which the ripe seeds are ejected.

This article is not intended to furnish complete list of curious resemblances which occur in nature, but merely to point out a few of the more striking, and to out a new or the more striking, and to show how they may be utilized, as aids in teaching. If the reader will exercise his own powers of observation and imagination, he will experience no difficulty in discovering a well-night endless serie subjects. In the patterns displayed by insect's wings many very diverting de sects whigh many very diverting designs and pictures may be traced, four of which we illustrated. Perhaps the most striking of all is the "80" mark on the bludwing of the South American butterflies called Caiagramma. Of course the figures are not perfectly distinct in every species of the genus; but generally the hind-wing displays on its under-surface a more or less obvious "80" or "88." Hence, collec tors in Brazil often term these butterfi "eighty-eights." The white markings The white markings on the thorax of the so-called "death's head" moths are also very impressive, being a very good imitation of a skull and cro s, and reminding one of the insignia of a famous German cavalry regiment. In German Poland, where the moth is espederman Fusion, where the mous is septerally common, it is known by such names as the "death's head phantom," and the "wandering death-bird," and is the object of much dread among ignorant peasantr. The great Indian "snake" moth (Attori atlas) gets its name from the fact that len-masses, or the clips from which the the tip of each fore-wing suggests the police has been detached, fixed firmly to bead of an angry cobra seen in profile. The very remarkable flower-spike, or in-curious and beautiful designs upon their florescence, of the sweet sedge (Acorus wings, witness the "drooping but" discussional deserves mention because of its played on each fore-wing of the well and the winds and the work of the well and the work of the work of the well and the work of the the tip of each fore-wing suggests the known "moon" moth (Acties land). These and many other patterns on the wines and many other patterns on the wings of butterflies and moths constitute a stora-house to which a rities and designers might well go when they stand in need of in spiration. Indeed, certain conventional designs almost certainly trace their origin to the wines of unands. The farsons in to the wings of insects. The famous Indian and Cashmere shawls, for examp reproduce in their patterns the colors and markings of butterflies which belong to the genus Cethoeia,

As to the manner in which Natu duces these designs on the wings of but-terflies and moths, the following brief description may be given—this being really important point to which the tr tery interest aroused by the designs t serves should be made to lead. The

clothed with a more or less dense growth of hairs. Now these hairs Nature has taken in hand as her material for picture-making. But she has not left them as mere hairs. She has modified them in a wonderful way. Butterflies and moths wonderm way. Butterfiles and moths make up the order Lepfdoptera—a word made up from two Greek substantives which signify respectively a "scale" and a "wing." Why? Because the membranes of these insects wings are clothed with a multitude of minute over-lapping scales. And these scales are really modified hairs They grow out from the wing membran in exactly the same way, while a complete series of transition from hairs to scales may often be found in a single species. hay orten be round in a single species.

As to the manner in which this modification may have proceeded, we shall gain a fairly clear idea in the following way.

Let us first think of a hair as a cylindrical bag closed at one end. If, now, we prebag closed at one end. If, now, we pre-sume this bag to be formed of an expan-sive but non-elastic material, we realize that it could be readily infasted and flat-lened. By this process, in fact, the cyli-drical bair could be converted into a flated scale; and there is little doubt that tened scale; and there is little doubt that in this way the scales of insects wore de-rived. Attached to the wing membrane by short stalks, and looking like so many little battledores or rackets of innumer-able queer forms, the scales are restly flattened hairs.

Now among certain primitive insects which live in dry situations, scales seem to be useful as a means of retarding evaporation. The quaint little creatures known popularly as "silver ladies" or "sil-ver fish" (Lepisma), which we find in our Their bodies are covered with a dense growth of beautiful slivery scales; and by this means a too rapid escape of moisture this means a too rapid escape of moisture from the surface of the body is presented. Indeed, none of the scateless silies of the "silver ladies" can live long in a dry atmosphere; they literally shrived up—Nature having intended them to dwell among moist surroundings. But in the case of butterflies and moths, no such purcase of butternies and motin, no such pur-pose is served by the scales; so that we may regard them simply as a basis for the development of color and color pat-terns. Nature uses them, so to speak, as so many stitches in a tapestry of marvel-

#### German Inventors and Office Furniture

IN the report of an exposition for office furniture held in April at Frankfort, it "rumiture need in April at Frankfort, it is said that the exposition furnished convincing ovidence of the increased interest taken among business concerns in Germany in improved office appliances and showed in improved office appliances and showed also that the German involvor and manu-facturer is alert to the value of trade in such appliances and is equipping himself to secure a larger ahare of it than he has heretofore had. Referring to typewriter exhibits, it is suggested that much stress was placed on the various things that the machine can do saids from ordinary type-writing and that it is safe to say that German inventive effort will be directed along these lines and that much will be German inventive enort will be directed along these lines and that much will be made of such improvements as selling points. If these features are of interest to German inventors, they should equally interest American inventors who have already done much to develop office ap-pliance and particularly along the type-writer improvements.

#### The International Congress of Zoology

THE International Congress of Zoology was held recently at Monaco under the patronage of Prince Albert, whose emithe patronage of Prince Albert, whose suit-nent position in occanographic work made this solic doubly fitting. It will be remem-hered that the original promoters of modegy congresses were the Franch action tists Mine-Edwards and Blanchard. The these Mine-Rowards and Blanchard. The congress in held every three years and assembled in the citize of Paris, Moscow, Chainteldas, Berlin, Lepdon, New York, Serpe and Gritts, it is probable that in 1926 in will be held at Budapest and in 1926 for Stone.

#### The Industrial Need of Technically Trained Men-V A Variety of Avenues Open to the Young Man of To-day

By A. B. Quincy

nel into which to direct his energies for the life before him, there are to-day a We will sup multitude of avenues open. We will a walk in life which is hased on one or other of the applications of science. This limits his choice somewhat, though not very greatly, for at the present day the majority of commercial and professional mands for a training based upon scien tific study. But what are the various sciences and their applications open to We will attempt no systematic order of commeration. Suppose we begin with the biological sciences. There is botany, at the root of all plant The farmer of to-day cumol afford ture. to be ignorant of the fundamental principles of botany, and who has not hear of the wonderful achievements of Lathe Burbank, based on an ingenious applica tion of the principles of heredity, which we only now beginning to unde But it is not only in the cultivated field that the applied botanist finds work to do. The dendrologist, specialist in the botany of trees, lakes care of our forests and tells us how to utilize their product to best advantage. Then there is the "plant doctor," akin to the veterinary surgeon, but giving his attention to plants instend of anima

And as a special branch of botany there is bacteriology. We have beard so much of bacteria as breeders of disease that we are perhaps sometimes apt to forget that we have friends among them as well as foor. There are first of all the seavence bacteria, without which we should be hard pressed to get rid of the sewage of our great cities. And there are bacteria in the soil, whose action is indispensable to the higher plants growing upon the soil Again, we have a number of fermentation industries depending upon bacterial ac tion—the manufacture of cheese, vinegar, beer sleohol, and so forth

The medical man is, of course, keenly interested in bacteria, not only as the cause of disease, but also the means for producing null-disease sora, of which the diphtheria antitoxin is the shiuing ex

Zoology chains its own share of the prizes won by modern industries. Her niso the application of the laws of heredits will in the future greatly assist th animal breeder in the proper selection of his stock And that delicate balance which is struck in nature, keeping each species in its proper proportion, has been studied with important results in certain cases where some one species threatened to become an unmitigated pest, unless it were possible to find an enemy who would feed on that species and thus keep it with in reasonable bounds

Another of the natural scie is commonly studied in conjunction with one or the other of the engineering sciences, although many will find it both pleasurable and to their advantage to specialize here. Geology fluis many applica tions, not only in the mining of coal, ores gens, building stone, and so forth, bu also in civil engineering, wherever founds tions have to be luid, a road built, or a water supply provided.

We have so far considered what might to entitle to further in sciences, as dis-tinguished from the "experimental" sci-ences, such as physics and chemistry. All oughiering is of course applied physics. person.

To the boy leaving high school and But at the present day looking about him for the best chan- cial branches of ongine ent day a number of spe ering have com into being, which are rather more closely connected with the parent science, and therefore require a particular familiarity with the principles of physics. As ex-amples may be mentioned telephony and telegraphy, both of the older type, and wireless

But we have not exhausted the scien One of the most important, to the bush ness man, we have not mentioned; econics. All husiness transactions fall in es transactions fall int the province of this science, though it no doubt interests particularly the banker the financier and the legislator. The truth is, no one should to-day be ignorant of the fundamental concepts of this scient Yet probably no science is so negle In one special field this science

late come into prominence, though its name is not often mentioned in this connection : namely, in efficiency engineering The basis of all our actions is the er despur to raise to a maximum the sun total of the pleasures which we can derive from our activities. Now one way to increase this pleasure is to either increase production without changing the labor re quired for il, or else lo leave production inged, while decreasing the labor in volved The "efficiency" engineer has come to show us how to do this The importance of his work rises pari passa with ie ratio which the cost of labor bear to the cost of materials in the production of a given commodity. An example may serve to illustrate this Suppose that for a certain article A the cost of material is \$10, the cost of lubur \$1, and that the efficiency engineer sleps in and reduces the labor item by one half, to 50 cents The total cost of the urticle has been changed from \$11 to \$10.50, or by about 5 per cent Now suppose that another article B costs \$1 for material, and \$1 If in this case the efficiency engineer reduces the cost of labor to 50 cents he has effected a saving of no less than 25 per cent! Anyone who has had unything to do with the manuf un article in which the cost of labor is the chief, or an important item, winppreciate the importance of this. will fully

No attempt has been made here to approach an exhaustive review of the dif terent fields of applied science to which the young man looking out upon life may turn . In point of fact, though his prin l attention may be given to one or which we cannot stop to consider, no me can afford to allow "specialization" degenerate into a more narrowing down to one thing, and the modern man of af folia must have more or less familiarity with several—the more, the better—of these disciplines. It is generally found that the specialist worthy of the name knows a great deal more about fields out-side his chosen one, than most others who do not claim to have specialized. And in framing his course of studies the young student will do well, so far as his means permit, to avoid premature specialization Once a good solid foundation of genera knowledge is gained, it may be very much rower field to which to pay special atten tion. And he may find it both cong and profitable to sleer somewhat off the old beaten tracks, and take up one of the newer developments of science. this he should be guided by the advice of ome thoroughly mature and competent

# Another new and decidedly progressive development in motor car construction will distinguish the 1914

There have been three important epochs in the development of the motor car. They were the three important epochs in the development of the Cadillac. The history of the Cadillac is the history of motor car progression.

#### The First Epoch:-

Eleven years ago the Cadillac Company produced the first practical and durable motor car in large numbers. How practical it was: how durable it was, the whole world knows, since these eleven year old Cadillacs are still in commission.

#### The Second Epoch:-

Five years ago the Cadillac Company, by massed production, scientific standardization and advanced manufacturing methods, was the first to demonstrate that it was possible to produce a high grade, powerful motor car to sell for less than \$2000.

The magnificent results of that demonstration are known wherever motor cars are driven:—the record of the cars as clean, as honorable to-day as the day they were built.

#### The Third Epoch:-

Two years ago the Cadillac Company first made possible a realization of the motorist's dream of an automatic electrical cranking and lighting system which banished to oblivion forever the awkward crank and the inefficient illumination.

Thus, three times have Cadillac policies and Cadillac principles left an indelible imprint upon the motor car industry.

Three times has the Cadillac Company accomplished that which was proclaimed impossible.

Three times has Cadillac progression set a pattern for almost universal adoption.

## The Fourth Epoch

And now a fourth epoch, a fourth period of progression as important as those preceding it, is soon to be inaugurated.

The Cadillac is about to endow the motor car with:-

A new element of efficiency A new quality of luxury A new source of economy

The Cadillac Company is not, as you know, given to false premises or to false promises.

This new development, like its predecessors, is destined to influence the trend of the entire industry.

Public endorsement of Cadillac development has always been more emphatic than our own claims or assertions concerning that development.

It will be so in this instance. Your recognition of these new advantages will be immediate.

Our next announcement will contain particulars.

Any expectations which this may arouse in your maind will, we feel sure, fall short of your enthusiasm when you know the facts.

#### Government Valuation of Railroads

IIE ruiing of the Supreme Court in the Minn sota rate case, which establishes the right of the States, where there is no Federal intervention, to regulate califord rates within their own borders, has aroused an inevitable fear among the investors and manners of our railroad systems that great injustice may be wrought in certain directions to the investors, and that the further development of our transportation facilities may be greatly retarded if not practically

Take, for instance, the ruling of the Supreme Court that the value of the right-of-way shall be determined by the current market value of similar land in its -a raling which it applied on hard-and-fast lines cannot fail to work very great injustice. Any one who has been concerned in the construction of new rullroads is well aware that the owners of binds through which the projected line is being inld are upt through which the projected line is being full are uple to ask exorbitant prices for the property that is re-quired for right of way, leaving to the milroad the choice of paying the price or resorting to the delay and expense of condemuntion findings approved by the court

We are well aware that in the building of ploneer railroads, cases have occurred where the desire of the public to obtain the advantages of railroad transports tion has led to an offer of a free right-of-way, should the rollroad be built, but we believe that these cases are comparatively rare; certainly liberality of this kind is not conspicuous in the inter development of existing railronds, particularly in the more populous parts of the United States It is evident that if valuations are to be made in strict conformity to this ruling of the Supreme Court, a grave injustice may be done the investor and the attitude of the Government may become nlmost contisentory in character.

Furthermore, we fall to understand on what basis f inw or equity the court should have ruled that, in estimating the value of right-of way, the interest charges, cost of acquisition and various contingencies should be excluded. Particularly in the case of some of the recently built and extremely costly roads, it can be proved that these expenses are very real and of large amount ('apital is proverbidly timid, and we can conceive of no conditions that would discourage the investor more effectually than the realization of the fact that at some subsequent day, in valuing the pr erty covered by his investment, the Government might se to recognize the large sums of money which had to be invested in excess of land values in the immedi-

in its rolling on the question of depreciation of values, the decision of the Supreme Court runs counter to well-established accounting practice, which has been to charge repairs and renewals to income and not to capital; and it seems to be opposed furthermore to the previous ratings of the Interstate Commerce Commission common consent, deprenation has been considered a liability of the stockholder, to be provided for from reserve funds and current earnings cortoinly it has never been regarded as a wastage of rapital. One of One of never neen regarract as a wasage or separation on the ladge railroad men, commenting on the ladgester of this ruling, quoics, once more, the familiar illustration of the ferryboal, which represents an lurest ment, say, of \$20,000 in a craft which having a life of 20) years is entitled to a return of 4 per cent annually for that period, and also operating expenses and un

amount each year which, in the aggregate, with inter est, will amortize the investment at the end of the twenty years. According to the ruling of the Supreme enth year the owner of at the end of the ulnete the ferryboat should be entitled to a return on the depreciated value of the boat only, or say \$1,000, instead of the full investment.

A savings bank investment would be better than this Some day, in a more remote future than its advo cates would have us believe, Government ownership of railways may receive national approval he made the subject of an net of Congress speak of the remote future, because we believe that the purification of our political life, of which there are araging signs, has not yet proceeded to the point hich our great and costly rallway system can be sufely intrusted to the tender mercles of multibul at pointees. A question of such vast importance us that of Government control of the railroads should be upprouched in a most conservative spirit, and with a keen sense of the high morni obligation of the Governmen to act in a fair and broad-minded spirit in the appruisal and purchase of these vast properties

#### A Word of Warning

THE daily press states that the British Navy has committed itself to the policy of oil fuel to the exclusion of coal for ships of all classes and sizes; also, the daily press and certain engineering ke it apparent that the l'uite the design of its latest buttleships is providing for all

It is inconceivable that Great Britain, owning no extensive oil fields, should commit herself irrevocubly to this poincy, and it is not believed that the United States Navy has so committed itself. We believe, rather, that the United States Navy desires simply to experiment in oil burning, and that its action in the case of three or four most recent ships is not to be regard as a precedent or as a fixed policy. This belief is insed well known fact that while the United State is in a better position as to a supply of oil fuel than is Great Britain, still the Government controls ve little oil-bearing land of known value. The opinio expressed by some experts as to the total known and probable supply of oil is that it scarcely equals five per cent of the total known and probable supply of coal ulso to be remarked that the oil supply is and controlled largely, if not exclusively, by well night uli powerful trusts, who are able to manipulate the prives to suit their convenience, or to withhold the supply absolutely if they see th

e records of all prices show that, whereas fue could be had at about 214 cents a gallon three or four years ago, it now costs from 4½ cents to 4½ cents per gallon. These prices may be accounted for by the fact that at the first mentioned date there had already developed a huge demand for gasoline, naphthas and other lighter fractions, so that the residual (about 50 per cent of the crude oil) represented a by-product for which there was no very great demand. Under these circumstances, the oil interests did everything humaniy possible to encourage and develop the advantages of burning oil for fuel, both in bind and marine ins Their arguments were that off burners required nttendance, less space for stowage, no handling of se, a quicker response to stemming denumes and that the fuel was actually cheaper than coal. These very attractive arguments woo the day and caus many new plants to be equipped for oil burning and any old plants to be converted from coal burning to oll burning

The action of the Standard Oil Company and its sui sidisty companies in the fall of 1912, by which they d to renew contracts with large customers failed to deliver the remired amounts under the their existing contracts, shows conclusively that the demand for crude oil and residual oil as fuel is now apace with the demand for the lighter fractions, so that the future of the oil interests will be to refine only a sufficlent amount of oil to so supply the demand for gas-line and naphthas us to keep the price of these products at the highest possible level. There will necessarily an ever increasing shortage to the supply of fuel oil, both residual and crude, so that we may expect a continual increasing price on this product. In fact, duce a horse-power by burning oil in the furnace of steam bollers than it does by burning coal, and the end is not yet in sight.

It is believed that the United States Navy should build its capital ships primarily as coal burners, providing oil stowage simply as an adjunct. The co availability of fuel are the only questions that need be considered, so far as the Navy is concerned, since the complement of a war vessel includes a sufficient number of men to handle the fuel and the refu having a supply of fuel oil to be used as an auxiliary rests in the fact that the limit to high speed steaming

is the failure of the personnel to get the coal to the is the failure of the personnel to get the coal 16 the furnaces. Hence, it is very desirable that the crews of vessels have sufficient experience in oil burning, so that in an engagement or chase at high speed, after the crew has become exhausted in fring with coal, the use of oil may be resorted to and the personne

the did not may be resident to continue at high speed.

It seems, therefore, that capital ships should not be designed us oil hurners, since a ship so designed cannot go to coal burning without a complete re ment of firerooms, boliers and furnaces. On the other hand, a ship designed primarily as a coal burner can use oil as an auxiliary without requiring any structural

#### Interstate Commerce Commission on the Stamford Wreck

TE larve before us the report of the Interstate Commerce Commission on the rear col-ilsion at Stamford, Conn., on June 12th, in which six imssengers were killed and twenty injured. The findings are based upon an impartial review of the facts as brought out in evidence and they will com-niend themselves to every one who has made an intellint study of the question.

Rear collisions are common enough—sadly too mon-on American railroads; and it may be asked why we select this particular collision for special comm-We do so for the reasons that the circumstances of the wreck are unusual and that they teach some valuable lessons which are summarised in the report

Renr collisions are duo generally to disregard of, or luability to see signals, or to disobedience to train orders. The present collision took place in day light, when the conditions for vision were good, the signals were properly set, and the engineer was doing the best ew how to obey the signals and avoid collision

We are entirely in agreement with the con of the report that the engineer did not have the special experience and instruction required for the operation of such a train. It takes judgment and experience to able the engineer of a heavy passenger train running sixty miles an hour to determine just when and how to apply his brakes in order to stop within a determtned distance. In such experience the engineer of this train was totally tacking. Work as a fireman, or un engineer handling freight and even slow pas trains, would not give him the necessary experience in this connection reference is made in the report to the testimony of the airbruke expert of the Pennsyl vania Railroad, who said that if it had been found necessary to send such an inexperienced man out on ch a train, a traveling engineer, or a road foreman of engines, would have been assigned to ride with him

The report lays stress upon the fact that when this engineer on his first trin in charge of a first-class passenger train, ran by a station and reported that the error was due to the brakes being out of order, no one in authority seems to have seen any necessity for a test, either of the man or the brakes, before he was again sent out on the same line of service We must confess that it is simply amazing that the first run of a new and inexperienced man with an important train not the subject of careful supervision, and that his fulture to properly brake his train, and the reason he assigned for his faiture, should have been overlooked by the company. Such carelessness justifies the re-port in stating that something is "out of gear" on a ratiroad where high-class trains may be given over to an uninstructed engineman

With regard to the condition of the equipment, the statement of the engineer as to something being wrong seems to be verified by the evidence of an expert from the Lackswanns road, who stated positively the, a train in the condition in which this train was found at the time of test (subsequently made) would not have been permitted to leave the terminal of his road in fast passenger train service. The Commission finds that the rullroad has no proper system of checking work reports, so as to determine whether or not the defects reported on locomotives are actually repaired. It seems incredible that such laxity could be possible on a modern first-class railroad. It was an invitation to such disaster as occurred.

The whole system of swiftly flying and extremely trains is safe from collision as far as the equipment is concerned, only if the Westinghouse air-brake is in perfect condition. This fine piece of mechanism, one of the most brilliant and successful inventions of the age, will do its work effectively, only if it is maintained in first-class condition. But like many another successful invention, it requires a thorough system of inspection and maintenance, and it is well understood that careless and too infrequent inspe ing may rob the air-brake of a great part of its effective braking power. On any well organized road, any report from an engineman of the elightest defect in the brakes would receive immediate attention

#### Engineering

Proposed Tunnel Bensath the Selent.—It is proposed to haild, an electrically operated and way connecting the left of Wight with the main land. The length of the line will be some four miles, and the route will be in a direct line between Stokes Bay on the maintain and Ryde on the Island, the crossing lying a little to the east at the point where passengers for London dissembarfs from the German steamers. The total estimated cost is \$3,750.

Panama Casal Excavation in May.—The total execution for May, at the Panama Canal, of 2,779,532 cutic yards brings the grand total of canal excavation for the first time beyond the 200,000,000 cubic-yard mark. There then remained to be excessed 17,401,167 online yards. The total for the month is made up largely of dry excavation in taking out the Culebra sides and of wet excavation representing the work of the dredges at the two sea-feril entrances to the canal.

Selve This Problem.—The largest transatiantic line now under construction will present to a head wind a cross-sectional area above water, including smoke-stacks, masts, etc., of about 9,500 square feet. If the ship were steaming at a reduced speed of 15 knots against a head wind of 65 miles velocity, how much horse-power would be necessary to overcome the wind pressures alone? We submit this problem to our readers.

A Diesel-eagined Ship for American Service.—The placing of the "Hagen," which is driven by Diesel eagines, in service from Port Arthur to Kingston and Toronto is of interest to the engineering world because this is the first large Diesel-engined ship to enter the American service exclusively. The "Hagen" is driven by an 850 horse-power Carels-Diesel, two-cycle marine engine. The ship made the Atlantic passage in 17 days, 22 hours, developing 800 horse-power at 97 revolutions and using three and one half tons of fuel per day. An excellent feature of the engine is the maneuvering shility, as shown in the builders' trial, when the vessel made 63 maneuvers in 41 minutes, reversing from full speed absend to full speed satern, qualities which were sagin demonstrated at Montreal, when the chaip was maneuvering through the looks in the canal.

One Way to Prevent Fire Losses. "Revidents in New York will remember the campaign of education which took place last year under the direction of Fire Commissioner Johnson. The movement took the form of a series of photographs of rooms, houses, and apartments in which there was practically no furniture whatsoever, but upon within policies had been issued, and it was intended to point the noral that the indiscriminate issuance of policies made the firebug's hudness a most profitable one. The greater cance exercised in the first sur nonths of the present year by the fire Insurance companies has been mainly responsible for a reduction, during this period, in the total fire loss, of \$2,382,685. The Commissioner estimates that the saving in wear and tear on the department apparatus due to a reduction of 1,850 fires has brought an additional saving of \$125,000 to the lety.

Excellent Sanitary Conditions at Panama.—That the Isthmus of Panama continues to present sanitary and health conditions comparable to those of the average city in the United States is shown by the report of the Department of Sanitation for the month of May, during which the annual average death rate among employees per thousand reschole the low figure of 7.63, of which 5.42 were due directly to figure of 7.63, of which 5.42 were due directly to figure of 7.63, of which 5.42 were due directly to figure of 7.63. The Improved Telegraphona.—A new form of Poulson's elegraphone has been patented in which a thin wire of tungsten steel is made to run rapidly between the poles of a small electro magnet in the receiving circuit of the telephone. In order to magnify the sounds a Brown telephone relay may be employed.

The Aerological Observatory in Teneriffe, recently catabilished under the auspices of the International Commission for Scientific Aeronautics, has been taken over hy the Spanish government and placed under the direction of Sedior Juan Garcia de Lomas Lobaton. Additional stations are to be established at Lower levels in the island.

Changes in the Map of Africa—The territory in northern Africa, recently conquered by Italy from Turkey, has been divided into two distinct colonies, viz., Tripolitams and Circasios, with eapitals at Tripoli and Bengas, respectively. A governor for each colony is to be appointed by the King of Italy upon the joint recommendation of the ministers of Colonies and of War.

Electrification Associated with Dust-clouds.—Prof. W. A. Douglas Rudge publishes in the Philosophical Magnesian the results of calaborate investigation showing that nearly all kinds of finely divided material when blown into a cloud by a current of air give rise to electrical charges upon the dust and upon the air. The nature of the charges upon the dust and upon the dark and upon the charges resident upon the dust particles depends upon the charges in the charges in the material of the charges in the material of the material of the material control of the material or the material of the material of

The Ninth International Congress of Hydrology, Climatology and Goology will be held at Madrid, October 15th to 22nd, 1013, under the patronace of II.M. the King of Spain. An international colhibition compressing paperprishe selectific material will be hold in connection with the congress. The congresses of this series deal mainly with the medical aspects of the series of the se

Experiments with Ripples.—At the recent conversations of the Royal Society, Porf. L. R. Wilberforceshowed how ripples may be produced on a water surface by a vibrating dipper and projected by intermittent light so as to appear stroboscopically in slow motion. A phonic whold drove a slotted disk which produced the internittence, the motion being transmitted by fluid fraction, whereby a very uniform rotation was obtained in

Prof. Rockwood Dead.—Dr. Charles Greene Rockwood, Jr., Professor Emeritus of Mathemation at Princeton since 1905, died on July 2nd. Prof Rockwood was born in New York in 1842, the son of Charles Ca. and Sarah Smith Rockwood. He was graduated from Yale in 1864, receiving his Ph.D. degree them 1866. He received the degree of A.M. fram Yale in 1867, from Bowdoin College in 1869 and frum Princeton in 1896.

A Novelty Among Agricultural Experiment Station Bulletian has just been suoud by the station of the University of Wyoming at Learnine, outstied "The Identification of the Woody Aster" (Stutien in No. 97, April, 1913). The bulletin in prunted on a sheet of earthward, folided once to make four pages. The first, (cover) page and the hast page contain photographs of the plant in question, which is poisonous and has caused the death of thousands of they in Wyoming; the second page contains a non-technical description; while on the third page is mounted, in behaviour style, an actual specimen of the sets, in blosharium style, an actual specimen of the sets, in blosharium style, an actual specimen of the sets, in blosharium style, an actual specimen of the sets, in blosharium style, an actual specimen of the sets, in blosharium style and the sets of the set of the

"The Barocyclonometer for Use In the North Atlantic" is the title of a pamphlet by Rev. José Algué, S. J. which has puts been published by the Philippine Weather Bureau at Manila. An account of this instrument in its original form, as used for many years past by mariners in the Par Reat for the purpose of defermining the proximity, direction and movement of typhoons, was published in the Schrittine American of October 10th, 1912, p. 328. It has been materially modified by its inventor for use on the Atlantic.

Measuring the Stress Distribution in Transparent Makerlain.—Prof. & O. Coke has devised an apparatus for measuring the principal stresses at any point in a plate subjected to plane stress. This he accomplishes by measuring their sum and difference separately. The sum proportional to the change of thickness of the plate, and is measured at any section by a special form of extensementer reading to half a millionth of an inch. The difference at the same section is obtained from observations of the soulce bands shown in polarized light.

Lindenberg Observatory, the premier aerological institution of Europe, on December 31st, 1912, completed ten
years of daily upper-air observations with kites and captive ballooms. In spite of overy variety of unfavorable
weather, including furious gales, heavy fog, severe thunderstorms, lee deposits on the kite-wires, etc., observations were not omitted on a single day of that period, and
the total number of assents amounted to 5,659. No other
observatory in the world approaches this record. During
the first two of these years the ascents were made at
Tegel, the original site of the observatory. Besidest the
routine daily observations above mentioned numerous
ascents of pilot-balloons and sounding-balloons have been
made.

#### Aeronautics

The First Aeronautical Scholarship has just been won by a student at St. John's elementary school, Ealing, England. The scholarship is the gift of Mr. Grabame-White, and entitles the holder to three years' seromautical training at Hendon.

Zespells to Attempt Transatlantle Flight.—Count von Zespeln is bulled in largest dirigible with a view to crossing the Atlantic to the United States in the late summer. He expects to make the trip from thirty to sixty hours' time. German warships are to be distributed along the course to assist the airship in case it is obliged to descend.

Supporting Wheels for Aeroplanes.—Harry A. Ormeof Wesley Heights, D. C., has secured a patent, No. 1,063,386, for an aeroplane in which the wheels are mounted in frames which are protected to the plane of the aeroplane so that they can swing outwardly in opposite directions, means being provided for elevating the wheel frames ontwardly and laterally in the operation of the apparatus.

Equilibrium Device for Flying Machines.—Frederick William Dufwa of Mexico, has patented No. 1,005,033, an improvement in thing machines in which a rudder is mounted to swing sidewise and a swinging car is connected by a flexible connection with the rudder so that a side dip or invitination of the machine will automatically swing the rudder to re-ostablish the equilibrium.

An Aeroplane Improvement,—Halvor Olsen Elane of Sau Dego, Cul., has patented an acroplane in which there is provided in connection with a frame, a horizontal adjustable plane which may be adjusted by means of spaced vertical planes which may be adjusted for bodily movement in a lateral direction by the air and are operatively connected with the adjustable horizontal plane. The patent is No. 1,1662,772.

norrountal piane. The patent is No. 1,062,772.

New Steering Gears for Aeroplanes. 1-n patent No. 1,062,055, to Rene Tampier of Paris, France, is shown a steering mechanism for aeroplanes in which the rudder is capable of movement about a vertical axis and about an orbique axis which is strelf movement, and about an oblique axis which is strelf movement being controlled in its several movements by means of two liand wheels and bearing mounted at three transpolarly arranged points so it can be actuated as above described.

An Aeroplane Flight from England to India will, says the Landon Times, be attempted next October by Mr G M Dyott, who is now making cross-country flights in South America, the undertaking being, however, contingent upon the completion of a guarantee fund, which now amounts to about 11,000 The proposed route is by way of France, Sielly, Alexandria. Curo, Khartun, Suakin, Aden, and Karseln At the end of the flight it is proposed to present the aeroplane to the Government of India.

No Royalties on Wright Machines, it does not seem to be generally known that the Wright Company no longer charges royalty for the use of their machines for childition flying. As a matter of fact no flying royalties have been charged since January 1st, 1913. The Wright Company has deceiled, because of the greater competition in the exhibition business this year, to give their patrons still greater advantage by discontinuing the royalty charge for exhibition work. This means that the purchaser of a Wright machine will have the free and unrestreted use of the machine.

A Texas Flying Machine Patent—In patent No 1,036,772, Frank M. Bell of El Paso, Texas, shows a flying machine of hiphane form with two engines located below the lower plane and two concentre propeller shafts seak equipped with a propeller and located between the two planes with gearing from the organism of the propeller shafts and propeller shafts are propeller shafts and convergence of the control of the co

Pilot Statistics. "The International Aeronautic Foderation has recoulty published its animal bulletin, and it contains a lot of sevenants in all countries who are regularly entered. Up to the ord of last year the number of sevenance pulots is as follows: France, 96, Great Britain, 370, Gremany, 355, United States, 1931, Italy, 1989; Russai, 192, Austria, 84, Belgium, 89, Switzer-land, 27, Holland, 28, Argentina, 15, Spain, 15; Sweeden, 10, etc. Piolot of spherical bullours are as follows: Germany, 900; France, 294; Austria, 80; Italy, 07, Belgium, 85; United States, 42, Great Britain, 25, Switzer-land, 30; Spain, 30, Holland, 17, Sweden, 17, Argenina, 13, etc. As to pilots of surlsips, the number its Austria, 24, France, 23, Germany, 22; Italy, 13; Great Britain, 12, United States, 3, etc.

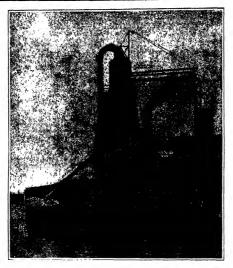

#### A Floating Pneumatic Elevating and Grain Discharging Plant

By Frederick C. Coleman

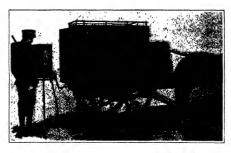

A N interesting floating imenmatic eletion has just recently been put into service at Emden, the rapidly-developing German port on the North Sea at the mouth of the river Ems. The elevator, which was built by Messrs Gebruder Seek of Dresden for the Elevator Gesellschaft of Emden, is illustrated in the photographs and consists of a floating iron pontoon, in which there are divisions for boiler and engine installations, together with living, engine institutions, together with every kitchen and invatory accommodation for the stuff, and anale storage room for materials. The machinery installation in the pontoon consists of one compound vertical steam engine, connected with the necessary air pumps of vertical type to which they are direct coupled. The speed of the steam engine can be varied even when running by means of a hand wheel and regulator on the shuft. In the same room as the steam engine for driving the pumps are the condensation apparatus, the Leuz and bother feed pumps and a special engine for the production of light and power, which is also of vertical type and coupled direct. There is also a third steam engine with a beit drive for a small dynamo to produce electric energy for The engines, pumps and power purposes. The engines, pumps and gears receive their steam from the botter, gents receive their steam from lie holter, arranged close to the enclue-room, and work at a pressure of 12 atmospheres. To the left and the right of the holter room are the root stores and the water tank from which the holters are fed. Above the engine room is the from mast which carries the pneumatic transport apparatus and weighlug machines As n be gathered from our illustrations, n por be gathered from our illustrations, in por-tion of the must is covered with sheet iron and is provided with staircase, plat-form, whallows, doors, etc., and the whole is well fixed to the floating pontoon. On the top of the tower, at the platform level, are placed the receiver and discharger of the transport installation, and to these are connected four carrying tubes which are made mavable both vertically and horisontally, and are fitted at the ends with suction nozzles so that the amount of air suction mozzies so that the amount of a carried up with the grain can be regulated to a nicety. Pipes are then led from the receiver to the pumps and air vessel, which are fixed on the side of the tower To meet delays which might occur dur-

ing weighing operations or by disturb-ances in the air lock, there are provided inlet valves as well as automatic safety valves, arranged in the air tubing and air chamber, which come lute operation when the normal working pressure is exce In the olr clumber is also an arrange ment to prevent grain being carried over into the same To prevent any dust entering these there is arranged in the interior of the receiver and discharger patent dust-collecting arrangement. This separates the dust from the grain, and allows them to mix only after the lutter has passed through the vacuum chambe of the receiver. A special advantage of this arrangement is that complicated cloth or water filters are avoided, and thus there is a great saving of space and labor. The whole tostaliation is very simple and entirely automatic. Below the receiver is the discharging device, which is adjustable and driven by an electric motor The current is regulated by a switchgear, set at a specified resistance, and if this is exceeded (which happens under abnormal conditions) the power is automatic ally switched off so that both discharger Beneath the and motor stop working discharging device an iron hopper is ar ranged with a double silde, from which the grain is fed into an automatic weigh er Thence the grain is brought into an other hopper and then by means of tele scopic tubing it is discharged into small

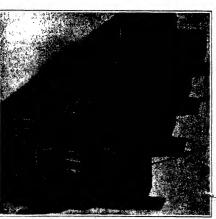

The plant is arranged to take a sack ing machine of a capacity of 50 tons per hour, and will empty steamers and load lighters (in bulk) at the rate of 120 tons

#### Purifying Water by the Action of Ultra-violet Light

By Dr. M. von Recklingh

T to highly important that a good drinkng water shall be free from microbe because many disease germs, such as the bacteria of typhoid, cholera, etc., are transmitted by water. A single person has caused infection to springs with typhoid and thus caused epidemics in which many people died. Hence modern hygienics de mands, first of all, sound drinking water for public distribution as well as for private use. Many springs deliver good wh some water, very low in their microbic contents, particularly in bacterium coli. How can these sources deliver pure water if they are supplied with water from riv-ers or effuents heavily charged with the ers or convents neverly charged with arrefuse of towns and villages? Simply by following the methods of nature. Nature employs two means for purification. The lirst is the action of sun or daylight on the microbes Soating in the water. It the microbes floating in the water. It has long been known that the sun has so strong a bactericidal effect, that rivers are purified some miles below the entrance of city effinent, so that the water contains scarcely more microbes than before entering the city.

fur purifying water, is filtration over nat-ural sand beds, such as river alluvials, thereby mechanically freeling the water of suspended matter and of germs. Until recently only the latter process

has been artificially employed. For nearly eighty years water plants have been provided with sand filter beds so that the water which they deliver is nearly always physically good. In other words, it is free from suspended matter. Bacteriologically, however, the water is not always up to the standard which mod-crn hygienics demands. For instance, Miquel, the famous French water hygienist, demands for water of the very be quality a microhic content not higher than ten per cubic centimeter. And the number of bacterium coli must not exceed ten per thousand cubic centim To obtain such results the first one of the above mentioned natural methods of killing microbes is now practically applied; ing incroces is now practically applied; namely, exposing water to a strong light. The strong bactericidal or ateri-izing action of the sunlight is due to the ultra-violet rays in the solar spectrum. Hence, we must choose a light which is extremely rich in these ultra-violet rays. We must create a miniature "artificial sun." In the quartz mercury vapor lamp, which closely followed the fundamental work done by P. C. Hewitt in illuminati mercury vapor lamps, such a source of ultra-violet rays has been found.

Purification, or sterilluation, of water y ultra-violet rays has become increasingly important within the last three years. The principles which form the basis of the water sterilization by mer-

basis of the water sterilization by mer-cury quarts lamps are as follows: First. Water, being easily penetrated by ultra-violet rays, may be exposed in a thick layer to the rays. But the water

must be free from floating matter.
Usually it must first be filtered.
Second. The apparatus must be so arranged that the ultra-violet rays are produced with a minimum of electric energy; violet ray lamps must have an economical life.

Third. The apparatus must be so con-structed that the maximum amount of ultra-violet light enters the water. In other words, as little light as possible should be lost.

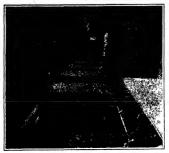

Fourth. The apparatus must be so con

structed that the water passes under influence of the strong light several ti This is effected either by leading the ded an enne in

## Shooting at Moving Pictures

Rear of the steel screen, showing the steel balls that

W ILD game hunting with no game warden about and open season all summer can now be enjoyed by the city-bound hunter. The happy hunting ground is at Coney Island, where moving picture animals in englistic settings examper across the far end of a shooting gallery for the accommodation of aspiring marksmen. The only departure from reclaim is that the animals do not fall dead when shot, but by a very lurgestious mechanism a record is made of the hits, and the scores of the different riches are kept segrately.

Two weeks ago the Scientific American described the moving picture targets used for the training of sharpshooters in the British army, in connection with

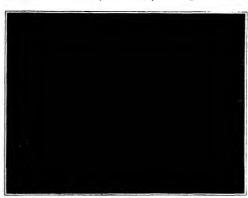

which a sound actuated mechanism isntern for an instant as soon as a abot is fired, so that the result may be determined by noting the tear in the screen. The fundamental in the screen. The fundament difficulty with this system of m ing targets lies in the fact that the animals appear to move, whereas they do not actually move, but are merely seen in different momentarily fixed positions. For instance, an animal which occupies a certain post tion in one picture may in the very next picture occupy a position several inches away. The eye supplies the illusion of moving from one spot to the other, while the picture animal does not actually traver distance. If the rifle is fired when the animal appears to occupy a point intermediate between the two actual positions, it will strike the screen between pictures, and a miss will be recorded. This difficulty has been very successfully overcome in the system illustrated in the accompanying engravings, the inventor of which is Mr. Eliot Keen.

The screen on which the pictures are projected is a steel plate about eight feet square and painted white. At the back of this plate a wooden

gridiero supports small from helis hung on short pieces of chain arranged so that the impact of the builtet on any point on the steel screen will drive a hall away from the plate, extening the chain to cross, two rods, thus closing a break in an electric cirvuit. Only the rods immediately behind the target are energiesd, so that a hit will be electrically recorded if the builtet arises the target. Otherwise the apparatus will solute a miss. One of the accompanying photographs shows the back of the steel screen with the balls attached to it and the rode running across it. The balls are three inches apart. The rode run hortsontally, but every other one is connected with a vertical wire. We may liken the horisontal rode to parallel of latitude and the vertical wire to meridians or lines of inogratide. by which any spec on the screen may be fixed, just as on a map. Having determined the latitude and longitude of the different points that will be compled by the

the vertical and horizontal lines crossing at these points at the particular moment when they will be traversed by the moving target. This is done by using sets of contact fingers on each side of the film in the projection mechanism and cutting perforations in the film through which various combinations of fingers may make contact to close the circuit of the corresponding parallels and meridians of the serven.

As shown in one of our illustrations there are nine fingers on one side to control the paralicis and nine fingers on the other to control the meridians. These fingers operate in pairs of various combinations to close the circuit of relays which in turn operate to energize

Relay board actuated by the contact fingers and energizing the rods behind the acreen.

the corresponding rods. By using intermediate relays, nine fingers are enough to control three or four times as many rods.

In preparing a film it is thrown up by means of a weak light upon a chart which shows the location of the wires and the balls of the large target board. The operator looking at the projected image of the first because of the first season of the first because the size of the first season of the fi

fingers us they drop through the perforations of the succeeding picture on the film. The 'vlui' spot on the animal never purses, on of the sensitive area in the serven. It is not to be supposed that a builet must actually strike the steed cartion at the very notion behind which the bull is resting. There is no spot on the screen that is dead. If a bullet should strike mulway between two builts both of them would be thrown outward, making contact with their respective roles. This between two successive positions of the animal, and through which by the Illusion of the kinemiorarph the animal appears actually to move, the screen is sensitive, and simple in bullet strike are intermediate spot, a bit

would be recorded. In other words, there is never a time when the libusion makes it impossible to score a

The lats and misses of each marksman are recorded by a series of lamps located before and above The circuit to these lamps is closed through his own gun trical connections to the different guns are made through a light flexible cord which does not interfere in the least with the shooting. The contact is made at the hummer when the gun is cocked and broken when the gun is fired. An electrically operated ratchet device steps n brush from the terminal of one lump to the terminal on the next lamp to the terminal on the next lamp circuit. A thining device is used to operate a circuit breaker. Every rifle is connected to its own "stepper" and scoring lamp. When the gun is fired, the thining device closes the circuit connecting the par-ticular gun with the steel target contacts for a fraction of a second If the shot is a hit during this interval an impulse lights the lamp by throwing a switch. If the shot is a miss the timer cuts the connection after the proper interval and the lump stays dark. The gan cocked

for the next shot steps the brush to the next lump and so on. Any number of rifles can be used, for the interval required for an impulse to reach the imp of each gun is hardly appreciable.

Automobiles of the Paris Fire Department.—The Paris fire department intools to double the equoetty afforded by its present automobile fire engines, by the use of affected unknowled the pumps, which will be of a lighter design than the ones already in use. The new engines will carry six men instead of fifteen. On the wagon truck is mounted a 100-gallon tank so as to the wagon truck is mounted a 100-gallon tank so as to the afford an immediate water supply for the hose so that a stream can be put on the fire at ones, while the consection is being made with the fire plug. This type of light engine is especially insteaded for fighting moderate-stand first during the daytime. The number of automobiles used by the chief firemen is also to be increased.

#### Wireless and Sound Signals as Aids to Navigation

#### By Louis E. Browne

EXPERIMENTS recently conducted on board the stematic states stematily "Woodington," in the stematic of the purpose of demonstrating the practicalities of the purpose of demonstrating the practicalities of detormining distance from a source of simultaneous welf-close telegraphic and sound waves as a means of facilitating mutgation in cogy weather, have been necepted by the Navy Department as concluder proof that this system, in time, can be developed to a likely degree of perfection

in time, can be developed to a min negree of perfection.

The moduling futurely which the experiments were made was very hard, but Nantucket Should light-meaning the could be duals seen for about the unities. The barronpeter stood at 30.11 and the sent was entire. Startly lightmear the light-shift, a contine was steered to the westward for a distance of eight indice, and then, turning
to the southward and proceeding cost, the light-ship
wars passed on the post beam at a distance of 3.50 are
vards. Standing on for eight notes more and then
turning to the northward, a northwesterily course was
pursued passing the light-ship on the port beam at a
distance of 1000 vards. Then, turning southward, the
Washington' approached and passed near the light-

distance or root varias Trien, throngs someward, the Washington' approached and passed near the lightship on a southwesterly course at the close of the observations

The track of the 'Washington' in realism to the lightship is shown on the necompanying drawing by a continuous laked, him, which was determined by the rangetinder method, compass readings, and distances run, after making careful allowance for the third current thal was found to be setting generally to the north word during the experiments. a Hack chronometer, and the times of arrival of those from the submarine hell by a stop watch. The same observer noted both the wireless tick and the submarine-hell signal. For the velocity of sound in air at temperature of 64% dee, Fahr. a speed of 1,126 feet per second was used, and Dording's determination of the velocity of sound in water as 4,784 feet per second at 66 deg Fahr, was adopted

Interval of time between the receipt of the wireless and bell signals multiplied by the velocity of sound through the water will give the distance of the ship from the spot from which the signals are sent within three of four hundred feet.

For Instance:
The between wireless and bell 4 seconds
Velocity of sound in water 4,794 feet per second

librance of ship from bell. . 19,176 feet

Further tests are to be conducted by the Navy regarding the perfecting of the submarine signaling system. Furchar mitions have done much more to develop this system of signaling than has the United States It has been reported to the Department of Naval Intelligence that some of the big German ships can find their was that the harbor at Hamburg and up the river by means of the submarine bell and fog whistie checked up to the wireless.

#### The Competition for the New York, New Haven and Hartford Railroad Company's Automatic Stop

CHARLES S MELLEN'S offer of \$10,000 for the best automatic stopping and speed control device which would safely arrest trains disregarding fixed

some of the conditions required by steam suffice lines one of these being the ability of the device to work under all weather conditions and to be impervious to

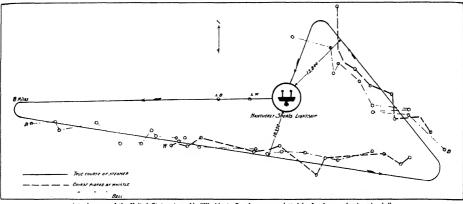

July 10, 181

Inasmuch as the approval of the Interstate Commerce Commission would be necessary before the New Haven would feel justified in putting a stopping device in regular operation, the requirements laid down by the Train Control Board have been adopted as well as sight additional ones made necessary by the peculiar conditions of the New Haven Illess.

Of the 704 devices of which plans and models have been submitted thus far, it is aunounced that not one has met condition No. 1, which reads: "The apparatus should be so constructed that the removal or failure of any essential part would cause the display of a stop signal and the application of the train brakes, and if electric circuits are employed, they should be so designated that the occurrence of a break, cross, or grunnd, or a failure of the source of energy in any of the circuits, should cause the display of a stop signal and the application of the train brakes."

A few of the devices already submitted might be perfected, it is said, so as to meet this requirement, and no dusht this will be done. A very large percentage of the devices have failed to embody any speed control feature, also one of the conditions, this being a provision that a train at a speed less than a pre-determined number of miles per hour might peas the automatic stopping device without application of the brakes. Also many have failed to meet the requirement that the device should work under snow, ice, sleet or freesing conditions.

All sorts of ideas are represented in the models and plans now in possession of Engineer Morrison. Most

Actual course of the United States steamship "Washington" and course as plotted by fog horn and submarine bell.

Signals from the light-ship consisted of shaultimeous signals from the whreless-clearing inpuratus and the submarfine-bell at the linearity when the steam for whitels give a blant. At intervals of one unlimite the maximum hardwal at while the third cleakes attached to the whistle permitted it to not a sound blant was blown from the rogsvibistic. At the instant the whilethelies, the wireless operation thished a tick, of two or three seconds diaution and the rathe of the stifking mechanism of the submarfine bell was tripped. This was necomplished with absolute accurace, for it was exhaustively tested by the colneidence of all three signius when the observers were close to the flattaship.

The results of the expediments are shown on the drawing. The lock of the observing vessed with respect to the lightship, as computed from the distance traveled by sound in water, between the time of the arrival of the Herrian waves and the signals to on the submarine bell signal fixed to the bottom of the lightship, are connected by dots and dushes, while the bott, as deternimed by the distance traveled by sound in all, between the times of arrival of the Herrian waves and the signals from the steam for whistle, are connected by

A remarkable feature of the tests was limit his sounds from the steam log-whilste were best after steaming half a mile to the westward of the likhriship, at the beginning of the experiments but in the run the eastward they were carried all the was through word the submarine bell signals were lost but four times. The times of arrival of the wireless signals and the steam for white the grants were lost but four times.

signals, expired on July 1st. On that date 2,816 persons in all had entered the competition. The applicants represent every country, including China, Japan, and Australia

While a total of 2.410 persons have responded to the original offer and may be said to have a tered the competition, only 704 of the applicants thus far have substitute plants in reply to the circular sent to such as plicant giving the conditions and requirements of the competition. This recent is to be acceptable a device must be adopted for general use by either the New Intellectual President and Presid

The amount of lallor involved in President Melleu's ofter may be estimated from the fact that C. H Morrison, chief signal engineer of the New Haven, who has been placed in charge of the competition, up to July lot laid written 4.082 letters, and 1,483 copies of patcuts but been clustual from the Metantic Office.

cuts had been obtained from the Patent Office. The of the reasons underlying Freedest Mellou's offer was the fact that at the present time there is no automatic stopping device in requiral operation on any of the steam surface roads of this country, though some roads are conducting experimental rests. The New Haven road, however, is the only road which has thus far offered a reward to inventors for such a device. The stopping devices operated on some elevated and subway lines, notably in the New York subway, while effective on such lines, have not been designed to meet

of them show that the inventors, while intent on rul alling some of the eighteen requirements specified in the circular, have totally disregarded others, particuiarly that one providing that the failure of the device to work, such as might be caused, for instance, by a person tampering with it, would of itself cause it to stop the Irais

Despite the fact that not all of the requirements have been met, the railroad will proceed at once to test the more meritorious of the devices submitted. These tests will begin the middle of this mouth, and will take place on the western division between Hartford and Newlagian. The two nutuants stap systems coming the near-to oil of the requirements will be tested first. One is the invention of Gene Webb, and is the property of the International Signal Company. The other is the luvention of un engineer of the Union Switch and Signal Company. The state of the International Signal Company. The other is the luvention of un engineer of the Union Switch and Signal Company. The other is the luvention of un engineer of the Union Switch and Signal Company. These will be bested out from a third rail. The tests of these and other systems submitted may take a year, but it is necessary to see how they meet all weather conditions. A bosomotive will be equipped with each device and operated over the track selected and on which the stop has been installed.

Obviously so award can be made until the expiration of the year 1915, as until then every invarior who has entered the competition has a chance so to perfect his device as to make it acceptable. The reward, under the conditions announced, is to be paid on the order of the Interactic Commerce Commission, the Masseckusesta Railroad Commission and the Connecticut Public Utilities Commission.

#### Lifeboats Which Can Be Launched on Either Beam

To the Editor of the SCIENTIFIC AMERICAN.

With reference to the article appearing under the allow me to correct the statement that the last, allow me to correct the statement that the Flushing steamers are owned by the Netherland State Railways. These steamers are owned and operated by a separate corporation, namely, the Zeeland Steamship Company. are owned and

At the same time I would like to draw your assention to the fact that the devices by which lifeboats can be launched from either side of the vessel, has not only been installed on the night steamers of the Pitukhing line, as day steamers of this company, running between Queenboro and Flushing, have for the control of th At the same time I would like to draw your atten running tesseen the recommendation of the saving device has been introduced on the Flushing steamers, namely, an accumulator bettery, situated near the writeless room far above the water level. In case the ship's dynamo should be stopped for any reason, its work is taken up automatically by this accumulator battery, which develops enough power to keep the wireless apparatus in opegation for about eight hours after the dynamo stops. New York city. C. Baxker, General Agent.

#### The Inventor and Price Fixing

To the Editor of the SCIENTIFIC AMERICAN:

I have read with very much gratification the article n "Benefits of Our Patent System—the Difference tween Monopoly and Patent Protection," B. Fay of Cleveland. It seems to me that no one could read this article without getting a very clear idea of the difference between the illegal monopoly and the monopoly granted by the patent system. The article excellently supplements the vindication of the patent monopoly set out in the minerity report accompany-

ng the Oldneid out
Referring to the recent decision of the Supreme
Court of the United States declaring that the patentee
has no right to control the price of the patented article has no right to control the price of the patented article after the ownership has passed from him, it occurs to me that there is a misconception as to what actually takes place in the sale of the patented article where the patentee fixes the final selling price. In such case, the seller retaining the right to fix the price, as has been done in safety razors and other things, it is clear to my mind that the patentise or seller has not parted with his complete title in the article. He retains enough of title in the vended articles to entitle him to say at

what price the articles shall be sold The transaction is very much akin to conditional ales, well recognized in common law, where the vendor tains title in the articles of merchandise until he has fully received his pay, and yet for all practical purposes, so far as the vendee or merchant is concerned, he h bought the goods outright, subject, of course, to this remnant of title left to the vendor. If the owner of a patent retains the right to fix the selling price, he is, in a similar manner, retaining a portion of his title that would legally give him the right to dictate the selling

which his goods shall be sold, the value of his monopoly is gone, a fact that has been abundantly preven in the history of many patented articles gotting into the of price cutters, as department stores and the This phase of the case, however, has been so abundantly manifested by much previous discussion that it is not necessary for me to suggest anything

scent decision is final, it seems to worth while for those interested in patent matters to work for restoration of the right of the patentee to fix the final selling price.

C. W. Dickinson.

#### The Maximum Parcel

To the Editor of the Scientific American: In your number of May 17th, 1913, Mr. Joseph

to tell in house

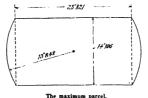

In your number of May 17th, 1913, Mr. Joseph Beeker has an interesting communication on the maximum parcel that can be accepted for transportation under the present Parcels Fost regulations, which prescribe that the sum of the rich and length must not acced 72 inches. Very Blady Mr. Beckar's Interpretation of the regular times agrees with that of the Post Office Department of the Post Office D

ment, but I venture to point out that it is not consistent with the wording of the regulations, which say "in measuring length the greatest dis-tance in a straight line between the two ends of the parcel shall be taken." If we have a rectanguthe parcel shall be taken. If we have a rectangu-lar package and take as its length the perpendicu-lar distance between the planes of the ends, we are using for the length not the "greatest" distance in straight line between two ends, but the a straight line between two ends, but the "least" distance between the two ends. The greatest distance in a straight line between the two ends of a rectangular package is obviously the diagonal of the solid.

In this case the largest rectangular package that can be accepted under the literal wording of the Parcels Post regulations is, using dimensions to three decimal places, 10.286 mehes square and 27.214 juches long on an edge, the diagonal being 30.857 luches. Such a package will contain 2,879

cubic inches only.

The very largest volume that can be accepted for Parcels Post transmission under the regulations be a cylinder with spherical ends, as indicated in the inclosed sketch which gives an axial section of the solid. The diameter of the cylinder will be, to the third decimal place, 14.106 inches, and the length of the side, to the third decimal place, will

he 23.821 inches, the cubical contents being 4,032 19

The problem of the maximum volume was paper, and a right cylinder with plan ends was given as a solution. This solution was open to the same objection pointed out above, namely, that for such a figure the length was not the greatest distance in a straight line between the two ends, but the least distance in a straight line between the two ends D. W. Tarlon,

Naval Constructor, U S.N Washington, D. C.

#### Grant Linton Replies to Mr. Hanna

To the Editor of the SCIENTIFIC AMERICAN Your same of date May 10th is at hand, containing your correspondent's criticism of my plan of aeroplane supporting surface design discussed in my letter of

Mr. Hanna claims that the sustaining force of the wire or eard constitutes of thelf an element in the equilibrium of the forces. This is indeed true, for, besides the one system of forces, namely, weight balanced by the vertical component of the air pressure or lift, there is the horizontal component of the air pressure there is the horizontal component of the air pressure or drift balanced by the sastaning cord, which latter system the writer omitted to mention in order to avoid complexing the problem. Mr. Hanna has confined these two distinct and entirely separato sets of forces Thus, the only appreciative effect the sustaining cord could possibly exert upon the vertical system is that caused by its own weight, which of courses would be negligible

Mr. Hanna challenges my assertion that the air is flowing horizontally at the forward edge of the fabric Is it necessary to mention that when the writer used the term horizontal he did so only to indicate the general direction of the line of flow of the air atream? Whether the direction of flow were horizontal or slightly divergent from the horizontal could not have a detrimental effect npon the proper working of the fabric Again, Mr. Hanna avers that at greater angles of

e than 30 degrees there will be a decrease incidence than 30 exgress those will be a decrease in the absolute lift of the air prossure, but an increase in the absolute drift, instead of a proportionate decrease in each case. Now we have Mr. Hanna's word for it farther down in his letter that "5 degrees is shout the maximum (angle of incidence) now found in efficient acroplanes," so that this fact then precludes the pos-sibility of the exception cited having any offect upon asibility of the plan proposed.

the reasoning of the plan proposed.

Mr. Hanná's confessed ignorance of the truth to my statement that "in both classes of vehicles the best efficiency could only be obtained by altering the length of the oord," is hard to reconcile with his own declara-

tion that "the late A. Cary Smith, by means of a trivance called the reach reef, which enabled the curva-ture of a sail to be varied manually at will, succeeded in substantially increasing the speed of a number of racing yachts." Evidently Mr. Hanna is unaware of the fact that exquisiteness of detail is just as an important matter, and more so in the design of the aeroplane than in the design of the sailing yacht, or that refinement existing models constitute es of itself the chief hope of the student of the heavier-than-air machine.

As an answer to Mr Hanna's contradiction of my statement that "full speed when once attained is as regular as that of the highest types of machinery, ne writer would cite as a particular instance the formance of Vedrines, the winner of the last contest for the Gordon-Bennett Aviation Trophy, at Clearing. Ill, September 9th, commenting upon which Major Samuel Reber says: "The speed at which he (Vedriues) made his fastest lap was 106 3 miles per hour, and that at which he made his slowest was 103.2 miles per hour,

at which no made instruction by the strength of the manning percentage variation in speed made in any lap from his average speed was I 8 percent, or in other words, a speed regulation obtained only in the highest types of automatic machinery." only in the indicate types of anomatic machinery.

As for the reference to reports of tests made on a Zodac hiplane, let the writer inform Mr Hanna that the biplane is by no means acknowledged the most highly specialized type of the heavier-than-air machine, also that though "the ability to vary the speed of horizontal flight within wide limits is a most desirable quality of the aeroplane, this feature (as attained at present) is only a proof of poor design, or at least of mefficient running

As an authority for "the helief in the parabola as only correct basic curve for wing sections," which Mr Hanna takes exception to next, the writer could quote no other than the Montgomery, whom Mr. Bauna mentions so often in his letter. How Mr. Hanna could have put any other construction upon my meaning than one identical with the behef held by the gentleman himself is a mystery to the present writer. Not to further intrude upon valuable space in what would be further intrude upon valuable space in what would be incre reiteration, therefore, the render is referred to the last paragraph of the letter in which the plan was originally proposed, where he will find the final answer to Mr. Hanna

When Mr. Hanna says, "I have often observed a piece of fabric suspended by one edge in a current of air, and I never saw one piece rise to a sufficiently acute angle of medeace for peroplane use without beginning to flap or undulate." he shows clearly that he has failed to grasp even the fundamental principle of the plan. for the undulating of the labric mentioned by him obviously could occur only when the speed of the air is such that the pressure exerted by it upon the fabric is vasily greater than the weight of the fabric itself. This condition is commonly seen when a piece of flexible This condition is commonly seen when a prece or assume fabric (necessarily very light unless loaded) is suspended in a wind of even moderate velocity, and it is quite clear, from his own description, that this is the condition Mr. Danua had in mind whon he made the statement quoted above. Then again Mr. Hunna fulls into a very grave error in assuming that, because the apward component of the an pressure is uniformly distributed over the surface, the total air pressure is likewise. Here he fails to take into consideration the

hkewise. Here he fails to take into consideration the effect of the horizontal or drift component of the pressure. In making a distinction between the two surfaces of the wing. Mr. Planna has introduced an entirely of the wing. Air rianna has introduced an entirely new particular, which for simplicity was omitted by the writer. The "singlo" surface is, of course, a com-promise between the two possible hest efficiencies of upper and hower surfaces; but, in consideration of the fact that, despite its undoubted inefficiency, manacroplanes use this type of wing, the writer felt limiself well within his rights in biniting an explanation of the application of the plan to this type alone. However, if Mr. Hanna really desires an answer to his query, the writer would suggest subjecting the upper and lower surfaces singly to the air flow, and then comparing the forms thus obtained (as regards angle of incidence, etc.) for an adjustment of relative loadings, and then joining the two together in the construction of a rigid plane. This system would have the added advantage of eliminating the modifying influence of the bars of metal objected to by Mr. Hanna, for these of course could be attached on the side of the fabric opposite that being subjected to the action of the air stream

Mr. Hanns has fasted to point out in his letter why an analogy between the action of the sail and the proed plan of aeroplane supporting surface design can-be admitted. The reason for this, as well as the suggested to me by Mr Guy Lowell of Boston, that, whereas we obviously are limited in a direct application of the plan to one point of suspension of the fabric, in the monoplane experimented with there were necessarily two, and in the yacht sail there are at least three

Bowmanville, Ontario, Canada,

### A Machine for Blowing Window Glass

#### The Remarkable Sievert Process

In the usual method of blowing window glass the workman takes up a globular mass of semi-liquid glass with the end of a long from tube and, by blowing through the take and reheating the glass at fatter vals, gradually transforms the built late a long, hellow, this walled eviluder. When this cylinder has cooled, the walled cylinder When this cylinder has cooled, the cubs are cul off, and it is still builthwise and functioned into a plane sheet of glass by heating and

me handral treatment.

In the Nevert process of blowing window glass by machine, which has been employed successfully in several European factories, a disk or cake of glass is first anide by pouring motion glass late an Iron ring by CFE 2, an insert in Fig. 1), reading on an iron called plate a. A blowing-head counserted with an air plue a is then brought down on the ring and attached to the When the glass has couled sufficiently the blowing-head and ring me lifted from the casting plate, carrying with them the cake of glass, which, being in plattic condition, sins, through the ring and meanness the form of a cup, which is then blown into cylindrical form by compressed air introduced through the play a. The Severt process, which can be employed for blowing holton glass vessels of all kinds, possesses the follow-

ing peculiar advantages.

1 The giass "head" of the cylinder or vessel is replaced by the metat blowing-head c, diminishing the quantity of glass wasted or re-meited

2 As this blowing-head may be of any diameter, it is possible to blow cylinders and vessels of extraordinary size

3 Severat shatlow vessels or flat objects can be blown at once with little waste of glass by blowing the cake of glass into a mold having a number of cuvities.

4. The time and skill required for the tedions operation of forming the ball of phostle giass by working the molten glass with the blowing tube are saved, as a cake of midform temperature and consistency is obtained simply to penting the molten glass into a ring laid in a casting plate
5. In the form of a cake of large area and com-

5 In the form of a cake of large area and communityely small thickness a very large quantity of glass can be blown at one operation, willout wasting much time in cooling the glass to the proper consistance.

Hence the process is most suitable for the production of flat objects, wide-mounted vessels and very large objects generally, and especially of cylinders destined to be transformed into sheet gimes. For these diverse uses the process and apparatus

For these diverse uses the process and apparatus have assumed various forms. An luxenious and elegant method of producing very large shallow vessels has been declased. The molten gines is poured on a molet assistato fell which is briskly slacken. The glass dances upon the layer of steam evolved by its own heat and spreads out lind in round cake of small and inform thickness which is blown by the pressure of the implement scann into the furered mold which is brought down upon it. The Dreaden Inventors have recently partented in a rrangement in which the inslication and is mainted on an axis, about which it is oscitlated by an electro-margacet device.

The Slevert process was first employed for the pro-

duction of very large glass vessels, such as both table and formenting vats. For this purpose an apparatus resembling that shown in Fig. 11s used, but the glass is poured, not on a special casting plure, but on the blowtur-head flseif, which is inverted. When the glass has couled sufficiently the apparatus is retinevered und the glass cacke, sagging through the rung, is blown downward into the most. In this case, the ring, which is very large, is made to several partie, which are separated to order to release the vessel.

In order to adapt the process to the blowing of extluders for windrox glass, several important changes were required. A both to be broad and shallow, but a window glass cylinder to long and comparatively narrow. Hence it was necessary, in order to distribute the glass uniformly over the whole length of the eyilider, to place leneath the matchine a deep heating from peculiar construction by which either the whole cylinder or any part of it, especially less pipper edge, could be reheated at my time. It was also necesasty to device a nafe my rapid method of attaching the blowing-head to, and detaching it from the ring which carries the glass cake or cylinder, by a mechanism capable of withstanding frequent and intense heating. This problem has been solved brilliantly plating in the rim of the blowing-head a circular

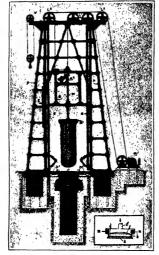

Fig. 1 and Fig. 2 (insert).—Sievert's window glass blowing machine.

electro-magnet mm (Fig 2), which holds the ring securely while the current is flowing and releases it instantly when the circuit is broken.

Two experimental machines for blowing window giass were tried, one in France, the other in Austria. The experience acquired with these machines was utilized in the construction of a third machine, which was put into operation in Suxony in October, 1900. This machine its litustrated in Fig. 1. A fixed frame of girders P, about 30 feet high, supports two vertical guide-rails S, along which the frame R can side up and down. The bidding frame R carries the isolwing-head B, and is raised and lowered by means of a steel wire rope, which runs over the pulley D and around the electrically driven which O'. Little force is required to move the stiding frame, because its weight

Fig. 3.—First Sievert machine for blowing large glass vessels.

is balanced by a counterpoise R, attached to a second wire rope that runs over the pulleys  $L^s$  and around the winch  $G^s$  in a direction opposite to that of the first rope. Safety clutches prevent the fall of the fram-with its load of glass in case of rupture of the rope with its loan of giase in case or replace at the lower suff of a fibellow vertical axis W, the upper end of which is connected, through a stuffing-box, to a compressed air conduit. This axis can be rotated by the motor G. conduit. This axis can be rotated by the motor or, mounted in the sliding-frame. The glass cylinder suspended from the blowing-head can thus be turned slowly without interrupting the blast of compressed air. Under the blowing-head and imbedded in the air. Under the blowing-nead and impeddes in the ground is the deep heating drum F, with its wider and dome-like top F. The lower part of the drum is not heated, but the dome contains a ring of gas-burners Q. by means of which any zone of the rotating glass cylinder can be heated at will by lowering the cylinder meror less deeply into the drum. The top of the heating drum can be closed by sliding over it the cover plates  $D^i\,D^s$ , which are moved by a third electric motor. By as of a fourth electric motor a car carrying a wooden bed-piate and traveling on the rails C can quickly be brought under the glass cylinder to support its lower end, if necessary. The cast cake of glass is brought beneath the blowing-head by a second car, which travels on the same rails. The starting levers of the four electric motors, the lever which makes and breaks the circuit of the electro-magnet on the blowing-head and the tap for the compressed air are placed together in an operating stand beside the main fram of the machine, so that one man can easily control and regulate every operation. This arrangement gives the process a great advantage over all entirely automatic methods of producing window glass.

The manner in which the cake of glass is fustened to the carrying rhag and the blowing-bend is shown in Fig. 2. The rlue h is Zeahaped in section, and the blowing-bend c curries a clicular rabbet d, which projects downward. When the blowing-hend is lowed upon the ring filled with glass the magnet m m takes firm hold of the upper or exterior flangs of the ring, while the edge of the soft cake of glass is placied tightly between the rabbet d and the vertical web of the ring, and also between the rabbet and the lower or interior damage of the ring. When the blowing-head is raised, therefore, it carries the ring and the sagging cake of glass up with it.

The whole operation of blowing a window glass cylinder with the machine is conducted as follows: The car, hearing the casting plate and carrying ring.

The cer, hearing the casting plate and carrying ring, is wheeled to the furnace, and the ring is filled with molten gloss by means of a indie, or otherwise. The car is then wheeled to lie blowing machine, which is provided with guides and stops that bring the center of the ring accurately under the center of the low-ing-head. The llowlung-head is now lowered on the ring and then ralsed, earlying with it the ring and the casks of gloss. Next, the car is removed, the cover plates of the heating fram are drawn aside and the cask of gloss, which has now sagged into the form of a bowl, is lowered into the drum and relastic, while it is rotated slowly by turning the blow-ing-head. When the glass has softened sufficiently it is holsted out of the heating dram.

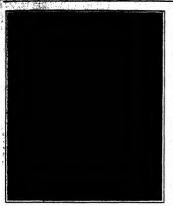

Fig. 4.—The cake of glass, sagging from the blowinghead, which has just lifted it from the car.

Fig. 5.—The car removed and the cake sagged into the shape of a bowl.

Fig. 6.—The finished cylinder suspended from the removing fork.

or three segments, according to its diameter. These cylindrical segments, like the hand-made cylinders, are transformed into plane sheets of glass in the flattening oven.

The capacity and efficiency of this machine were satisfactorily demonstrated by its performance during its first half year of practical service. The production of sheet glass per working hour increased from 25 square meters at the beginning of this period to 87 square meters at its close, and has since risen to 40 square meters. A carrying ring 65 centimeters (20 inches) in diameter, yielding critinders of the same diameter, was used, and the thickness of the glass was 2.5 millimeters (0.1 inch). The remarkable increase in production is attributable to increase in skill, particularly in the avoidance of breshage. At the end of the period it often happened that not one of the 110 to 116 cylinders made in a skill argely due to the uniformity in thickness produced by the construction of the heating drum. The hourly output can be increased by ming larger rings and by substituting for the ladie a mechanical filling system which will keep several rings, catting-plates and cars in operation, thus saving the time (about one minute) now wasted in waiting for the cake to col. The actual blowing of a cylinder occur.

The actual howing of a tyliner occupies only two or three minutes.

The glass is of remarkably good quality, uniform in thickness, free from air
bubbles and with a very even and glossy
surface. These results are due to the uniform temperature and thickness of the
cake of glass, its symmetrical position
with respect to the air tube and the employment of a vertical heating drum. In
the common method the bell of glass is
made up of portions taken up successively
by the blowing-tube and is, therefore,
likely to be neither symmetrical in shape
nor uniform in temperatures. The handmade cylinder, furthermore, is rebeated
in a horizontal position, and sie to
scratches, which are entirely excluded
when the vertical cylinder is anechanicsilv lowered into the heating drum with-

out touching the latter.

The new method of flattening also improves the product. The wide machine-made sylinder is split into two of three longitudinal segments which flatten almost sutomatically on the hot flattening stone. Hence they are exposed to little risk of injury from the iron flattening red, the treatment with the polishing block is shortened, the capacity of the 'flattening red, even is increased, and more viven and glossy surface is obstanced. Moss glass is wasted (4. s. prefarred to

Fig. 7.—The glass bowl lowered into the heating drum.

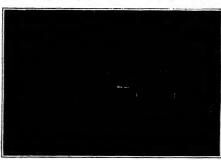

Fig. 8.—Cylinder in the tilting frame.

Pig. 8.—Glass segments stacked beside the flattening oven.

.

the melting pot) in the new process than in the old one, but this loss is more than compensated by the saving in wages and other operating expenses the process requires comparatively few workmen, who need not be skilled glass-blow-free the process of the process requires comparatively few workmen, who need not be skilled glass-blow-free the process required to the process of the

From the results obtained in the six months trial of the machine in Saxow it has been calculated that the cost of producing one square meter of glass, cul and packed for slipment, is more than its per cent less with the new process than with the old one. Another calculation, made independently by a Reighm expert, and based on Beigha working conditions, yields nearly the same result. Experience and the introduction of improvements, some of which have been montioned above, may be expected to increase the output and diminish the cost of production still further

The Slevert machine can be employed in the production of crackled, marbled and other varieties of sheet glass, in addition to common window glass, and it finds another important field in the production of glass bath tubs, kneading troughs, milk troughs, wash tubs, acid tanks and other large vessels The operation is conducted substantially in the manner described above for whidow glass cylinders, except that the glass is blown into a mold, if necessary, and the finished vessel is sent necessary, and the minimal vessel is some to an annealing oven instead of to a flat-tening oven. The production of large glass vessels by means of a tilting blow-ing-head into which the glass was poured has already been mentioned, but the Improved machine represented in Fig. 3 offers soveral advantages. The liability to breakage and uneven thickness and tension due to the tilting of the mass of soft glass is avoided, and the uniformity and gloss of the vessel can be improved by repeated dipping into the heating drum, while the electro magnetic suspension facilitates the entire operation. Glass vessels reinforced by wire netting have been made with the old machine and a still more intimate connection between the glass and the netting can be obtained with the improved machine and process

No glass is wasted in blowing vessels by this process as the thick rim that forms about the carrying ring is left on the finished vessel and increases its strength.

The contour of the ring and blowinghead must conform to the outline of the rim of the vessel, but vessels of different depths can be blown with the same ring and blowing-bend, and the diameter of the vessel can be varied somewhat by using, with the same blowing-head, carrying rings with vertical inward-stanting or outward-simiting web.

#### Do Animais See Things as We Do?

#### By J. Fidel Tristan, Costa Rica State College

A Li. the colors of the ralubow can be observed on the plumage of tiefts. Ture white and interess black are common; the most extraordinary shades are seen among the tropteal humanitar birds (Trocklitiae), some of them showing a metallic luster in many colors. The same can be said of diurnal butterflex, of coleopters and of larve

Naturalists generally try to explain tils variety of colors through the intervention of natural selection and number; When such an explanation is offered it is invariably usessued that ambins see things as we do. The writer helieves that many serious difficulties which have a refrequently most with which masking such psycholeses would subside if the assumption—unwarranted by facts to word when the ambine through most productive to the admirate kingdom, are adapted to one and the same scale of either undulations was producily left aside.

The many ways of living observed in anim imperious necessity of clearly seeing, in very different circumstances, either the game or the hunter, are so many factors which may cause the sight of animals to differ from ours - It is well known, for instance, that some birds can see small objects from a distance which causes them to be, for us, lost in a haze, created by the stmospheric diffusion of the blue and of the violet. Other birds, manmuis, and insects begin their quest for food after sunset, when light contains a high percentage of extreme red and infra-red ruys, which hardly make any impression upon our retina. In the tropica forest, a simple oil lamp will fetch an incredible num ber of butterfiles and other insects, the existence of which could not even be suspected during the day. These facts and many others seem to show that the eyes of some animals are probably more sensitive than ours to one or the other extreme of the spectrum, and that the relative hundrous value of colors may not be for such animals what it is for us. The results of the ollowing experiments, recently made by the writer, sem to him of such a nature as to lend additional force to this hypothesis; the following stuffed species were placed in a mass of green foliage: Ata militaris, Chysolis auripulliata, and Conurus potzii, two of them being partially or totally of such a green color as to be easily mistaken, at a distance, for a part of the Three photographs were tuken of the whole: one in visible light, one in ultra-violet light and one in infra-red light, the last two by means of Forcault's silver film and quartz lens and of Prof. Wood's cobalt glass and yellow film. On the photograph made in the infra-red light, the green plumage and fur, which do not reflect the infra-red, come out as dark spots over the clear field of the foliage, which strongly reflects Here we have two kinds of green, which look allke to the human eye and which would appear as entirely different to an eye which would be some at more sensitive than ours to the extreme red.

Another group photographed in the same manner is also reproduced, and the unmerous differences, seen at a glance, give an idea of how things would appear to any eye for which the scale of perceptible vibrations would have been either raised or lowered by even a

#### The Longest Aeroplane Flight

BRINDEJONC DES MOULINAIS, the French attman, landed at 4:20 oclock on July 2nd at the Villacoublay secondrume, near Vermilles, thus terminating his wonderful flight of about 3,000 miles from Parls to Rt. Peterbung and back and establishing a record for the longest aerial voyage so far accomvibled.

The following is a diary of the fight: June J. Paris to Warsaw, 803 miles: June 16, Warsaw to Drinds, 830 miles. June 18, Warsaw to Drinds, 830 miles, June 28, St. Federsburg & 184, 205 miles; June 28, St. Federsburg & 184, 205 miles; June 29, St. Scholand, 205 miles; June 29, St. Scholand, 205 miles; June 29, St. Scholand, 205 miles; June 20, St. Scholand, 205 miles; June 20, The Hague, 830 miles; June 2, The Hague 85 miles; June 2, The Hague 85 miles; June 2, The Hague 184, 240 miles.

M. des Moulinsis was escorted on the last stage of his great flight by French airmen.

## Results of the Prince Henry Aeroplane Circuit Race in Germany

FOR the third time there was held (in May last) in Germany a circuit race by German aeroplanes for the Prince Henry cup. This race lasted three days, and vn over a triangular circuit The cour from Wiesbaden to Cussel, from Cassel to Coblenz, and from Coblenz to Karlsruhe, a total distance of 354 miles. Nineteen machines started in the contest, of which seventeen fluished the first stage, four not arriving nutil the second day. Ten military acropic and three civil pilots made perfect flights. The flight the first day was made under good weather conditions, but the second day's flight was a difficult one, as a rauge of mountains had to be crossed and the weath was bad Only ten machines completed this stage. The third day's flight was made under excellent weather conditions. Four military and five civil pilots completed this stage, out of the eleven military and five civil pilots that started in the circuit. Following the circuit, two days of scouting were held by military chines only, in which twenty-three pilots started. trip to Strassburg was made with a stop at Pforzheim teen avintors landed and re-ascended at the latter place and seventeen arrived at Strassburg. Twelve left the next morning for the flux) flight to Freiberg and Neubreisach, where landings and reports were to be made, and of these nine returned to the starting point. The reconnoitering reports made while in flight were handed in at the various landing places and new tests were set for the aviators. These scouting flights in reality saved the event as far as the military aviators were concerned, for in the three days of cro flying many of the army aeroplanes suffered motor breakdowns. In awarding the cups, at the conclusion of the circuit, Prince Henry called attention to the lack of reliability shown in the motors

Lieut. Canter on his 57 horse-power Rumpler "Taube" monophine, wan the Emperor's cup for the best performance throughout the circuit, and also the second casts prize for retudility, as well as the Prince Henry

prize for the best performance in the military securing competition. Other important prises were won by Engineer Schlegei on a 100 horse-power Arstit monsplane, by Lieut. Joly on a 95 horse-power Gotha monsplane, by Lieut. Carganice on a 100 horse-power L v. d. blplane, and by Lieut. von Beaulien on a 95 horse-power Abstross biplane.

The First International Moving Picture Show CHAND CENTRAL PALACE in New York city was cliast week the center of the moving picture world. More than three thousand delegates from all parts of the United States and Europe were in attendance at the third annual convention of the Motion Picture Enhitor's League of America, which, in conjunction with the First International Exposition of the Motion Picture Art, opened on July 7th and lasted until July 12th.

Visitors at the exhibit saw low dinas are made from the raw material; how the leases and projectors are developed from rough glass and metals to the finished product; how the pictures are taken, and isst, but not least, how the completed film is thrown on the screen for the benefit of a public which has ceased to wonder at this recent product of actione. On the measurable floor there were four model picture theaters, to which admission was free.

One of the principal attractions proved to be a moring picture shooting gailery. Here for hours the visitor could safely fight photographic battles with fierce African gules and the sportsman could shoot at for or rabbits filting on the screen for all the world as if in real life. This apparatus is fully discussed on another page in this issue.

Kinemacolor pictures played an important part in the exhilit. Not only were the machines demonstrated at a booth on the main floor, but moving pictures in the original natural colors of the subjects were shown in the kinemacolor theater. In this theater exhibitions of the natural color process were given at hourly interval: It will be readily realized that such an apparatus as this, adaptable to a diversified list of subjects, is bound to prove of great beaneft to schenes.

Although moving pletures in colors were introduced something over a year ago a great many improvements have been made recently, especially in the color screen through which the light from the projector passes before striking the film. The latest type of kinemecolor machine has a new reviving color screen which per mits of adjustment in order to synchronize the acreen with the movinc film.

Color Bilndness in Astronomers.—Dr. Edward C. Pickering, Director of the Harvard College Observatory, has tested the sensitiveness of the eye to various rays of different colors for numerous astronomers by grouping their estimates of the light of the stars scoording to their color, as shown by the class of spectrum. The earliest estimates, those of Polemy and Sud, show results agreement of the color, as shown by the class of spectrum. The earliest estimates, those of the class of spectrum. There shows a marked sensitiveness to the red, and field to the blue rays. The latter effect is still more marked in photographic plates. All are referred to the Harvard standard, shown by the horizontal lines.

Bridge approach lighted by two doublereflector searchlights.

#### Double-reflector Searchlight for Automobiles By F. C. Perkins

PiCTURED in the accompanying illustration is a new mearchlight of German manufacture which is provided with a principal reflector and an auxiliary reflector. The principal reflector is a spheroid glass mirror, silvered on the reverse side and having an exceptionally large aperture ratio, the diameter of the free aperture and the focal length being respectively 10 and 8½ inches in the larger size and 8 and 2½ inches in the smaller size. It will thus be seen that increes in the smaller size. It will thus be seen that in view of the short distance of the fame or light source from the mirror, the latter gathers up a repriarge volume of light. The partly diagrammatic sectional view of the searchlight shows the auxiliary reflector first in its full light position in front of the light arce and then in the subdued light position off the light rays from the main reflector. It will be observed that in the latter position there is wide dis-persion of the rays of light, whereas in the other posionly is the light reflected from the prin reflector in the usual way, but it is also supplemented by the small auxiliary reflector. Only a small propor-tion of the light proceeding from the principal reflector is intercepted by the auxiliary reflector and this is made good several times over by its effect as an intensifier. On country roads the auxiliary reflector is turned to the full light position. When motoring through towns where gasoline searchlights are prohibit ed, the auxiliary reflector is turned through an angle of 180 degrees to the subdued light position, when the rays will be dispersed to such an extent as to give a general illumination. As the auxiliary reflector is ex posed to an intense heat, because of its nearness to the source of light, it is made of a special glass capable of resisting the effects of high temperature and abrupt changes. The front glass of the searchlight is made of the same material, which does away with the necessity of building it up of several strips. This naturally affords a far better protection from dust and dirt than a cover made up of strips.

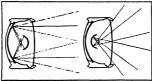

#### An Automatic Electric Light Plant By F. C. Coleman

N OTWITHSTANDING the large number of electric N generating stations that have been put into opera-tion during recent years, there are still many places devoid of a public supply of electricity. Numerous small plants have been constructed for lighting private houses, etc., situated in such localities, particularly since the advent of the internal combustion engine.

An interesting generating set of this description is manifectured in England, which starts and stops quite automatically, according to the load and condition of the storage battery. A plant of this type may be shut up in a room, where it will work without the alightest attention bayend filling of the gasoline tank and occu-

steation beyond filling of the gasoline tank and occasionally adding a little circulating water.

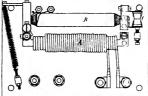

The singline is of the four-cycle type. Its cylinder is
water-faceheed and the top end is fitted with a removable covic. The vaires, which are well cooled, are of
pickel steel seel and are piaced in a side poolse. The carbeauther is of the constant level type and is supplied by
a small feed pump. It is claimed that it is impossible
for the extraorise to be fooded. Since the engine is
justeded in work without attention, it is evident that

Dispersed-light Full-light positi-Automobile searchlight with reversible auxiliary

Automatic electric lighting plant.

Relay switch providing automatic control.

act mounting of the lighting plan

the system of lubrication must be perfectly reliable and that oil must be supplied to the hearings as soon as the plant starts itself. To meet these conditions a force nump is provided. As soon as the engine commences to rotate, oll is pumped into the nulu bearings. afterward returned to the crank-case where a constant of oil is unintained Eugines of this built for all classes of service, and capable of working with gasoline or kerosene, or by using a special vaive, town gas can be used instead of liquid fuel. The whole of the plant, including engine, dynamo, controller, or automatic starting switch, and water tank, is mounted on two cross girders. Therefore the plant can be picked ap bodily and transferred to any new position with

The complete plant comprises the engine, dynan and a small battery, the capacity of the last being very much below that of an ordinary private electric lighting plant. When the battery is properly charged and no lights are connected to the circuit the engine remains at rest. On switching on a number of lamps so that the current does not exceed the normal dis-charge enpacity of the battery, the engine may still remain stationary until the voltage of the battery drops to a certain value. The engine then starts automatic ally and charges the battery. It will also start if the load exceeds the normal discharge rate. When the battery is charged and the lond is low enough to be ilt with by the battery alone, the engine stops run ning. Hence the battery cannot suffer owing to improper handling. The battery is charged at the times it needs charging, and the charge stops when the correct voltage per cell is reached. There is not the least doubt that a great deal of harm is done to the batteries of private plants by overcharging them, and automatic control should prove a great boon in this respect. Even if the automatic goar got out of order and the battery was damaged in consequence, it is to be remembered that the cells are small and can be renewed at comparatively little cost. We are told, however, that the control gear never does get out of order.

Turning now to the principle of operation, let us some that the small battery is fully charged and assume that he shall outer is this charged and that there is no load on the mains. Under these con-ditions the engine is at rest and there is no current flowing in the circuit. If, however, lamps are switched on which give rise to a load in excess of that which can be dealt with by the battery, the engine is started in the following manner: The current momentarily supplied by the battery passes through the series coil supplied by the battery passes through the series coil. A of the relax, which is mounted on the switchboard. The effect of this is to cause the upper of the two contacts C to be pulled down so us to form a councer tion with the counter below it. Current then passes into the dynamo and causes the latter to act as a motor and the engine is therefore run up to speed. To limit the starting current, however, a resistance switch is interposed in the circuit. This switch is fitted with a solenoid which gradually cuts out the resistance as in the case of a remote controlled electric motor. starting resistance is to be seen at the point A in the general view. The starting current of the set is rather small, because while the engine is being run up to sman, because while the engine is being run up to speed electrically the exhaust valve is lifted off its seat, and therefore no compression takes place. But when the arm of the starting switch reaches a certain

#### Price Maintenance and Modern Merchandising-III Price Protection Distinguished from Trust Control

By Louis D. Brandeis

ON May 14th, 1913, the Association of National Advertising Managers met at the Hotel Astor in New York and discussed the subject of price maintenance. Once of the Aprakers was Mr. Louis D. Brandels. In his address he very clearly shoved why the mointenance prices on patented and trade-marked orticles is not to have the manufacture prices by a trust. The following is an abstract of his lucid presentation, slightly edited to give his remarks more the character of an

The problem discussed by Mr. Brandeis has been considered from another angle by Mr. Henry B. Jou, president of the Packard Motor Car Company. "An article is not sold until it is purchard by the consumer," says Mr. Joy. "When you sell a hill of goods to the wholesafer or retailer, that is merely a step in the process of sele, which you naturally should have a right to control. The selling in their should and must include the right to control the intermediate agreeies of sale between you and mass measure the typic to thirty in bacteriarous openior. One deduced not and four real patron, the consumer, . . . The mensificativer must have the right to see that his goods reach the consumer with the least possible cost of intermediary processes. . . Then will the goods reach the consumer at the least possible cost, which it is to the interest of the manufacturer that they should do."—Entros.]

I can conceive of nothing more prejudence that the She dicial to the maintenance and extension of the right of a manufacturer to fix a protect the small m selling price to the consumer than to rail cuerally against the provisions of the Sherman inw, or against the attitude of the Government in endeavoring to enforce that beneficent statute.

The danger to busine fact that men have failed to draw the distinction between a manufacturer fixing the retail selling price of an article of his own creation, and to which he has imparted his reputation, and the fixing of prices by a monopoly or by a combination tending to a monopoly If what is desired were the perpelua-

tion of monopoly there would be no chance whntsoever, in my opinion, of preserving any existing right to make fixed selling es, or of extending further that right, us I think it should be extended; for the American people are wisely determined to restrict the existence and operation of pri-

The manufacturer's position is simply this: "That which is specifically mine, that which I create, and the good will which attends it—which was originally confined to my particular establishmen but now extends throughout the whole country, or perhaps throughout the whole world, that is my specific property; I have made it valuable to myself and I make it valuable to the consumer; because I inve endowed that specific property with qualities on which everyone who purchases my goods may rely. That cer taluty is of value to the consumer, as it is of value to the maker

Now, fixing prices under those circum stances has in it no element of monopoly Operating as an independent manufactur er under competitive conditions, you fix the price at your peril. If you fix it too high, one of two things is likely to hapoen; either the community won't buy it. or, if it does despite the high price, some other person will come in and share your prosperity—so long as you have a field open to competition; and the price will fall if there is no combination. To so fix the ultimate selling price in a competitive business is not a restraint of trade in any proper case. On the contrary, it stimu lates trade, because it gives an appropriate reward to the man who creates; and it is of the essence of trade to make as large as possible the rewards of successful crea-tion. As long as we maintain condition-favorable to competition and the freedom development which leave the individual's development untrammeled by superior power—so ions nov we safety allow men to take what profit they can get from an expectant pub lic, and to exercise the inrgest degree of liberty in the marketing of their products.

But the moment that you endeavor by a combination of superior power to clos the field to competition or to restrict indi vidual effort; the moment that you take away from the people that protection which comes from the incentive in the in dividual to create, and in the opportunity of the customer to discriminate in his pur chases (as you do when you close the avenues of compatition) them a grave danger arises to progress, and it is against such

printely directed. That statute seeks to protect the small man against the pov The Sherman law seeks to protec men in the right freely to compete, and to prevent practices which must result in to prevent practices which must result in suppressing competition. It seeks to pre-serve to the individual both the opportun-ity and the incentive to create; it seeks to encourage individual effort; and the right of an individual manufacturer in a competitive business to market his goods In his own way, by fixing, if he desires, the selling price to the consumer, is in the seiling price to the consumer, is in entire harmony with the underlying pur-pose of the Sherman law. But when men combine to form a monopoly, or control a particular line or branch of trade, however good may be their intentions, they necessarily curb individual effort. the fundamental laws of human nature and of trade they withdraw incentive from those who enjoy the monopoly, and they narrow the field of human effort by con-fining leadership to a comparatively few individuals. And even where a complete individuals. And even where a complete monopoly does not exist, a powerful com-bination makes it so difficult for others to enter the field that most men are prac-ticulty barred by the great chances of failure in entering upon so unequal a contest it is against such conditions that th Sherman law was directed. That is, the true restraint of trade-restraint through monopoly or combinations tending monopoly, a condition under which be ness success is at best temporary, is ofter delusive and is always purchased at the expense of the community.

Now I take it that the effort which was further the right (as it now exists in respect to patented articles) to fix selling prices to the ultimate consumers and which finds expression in Section 2 of the Oldfield bill proceeds from an admirable But though the motive is good and the purpose worthy, the course pur-sued is a mistaken one. And the mistake arises from the failure to recognise that certain hardships inflicted by conspicuous trusts which do fix prices, have not arisen from the fixing of the wholesale or retail prices, but from the fact that a monopoly or combination existed which made it nos to fix those prices at an unr ably high figure. In other words-it was not the fixing of the price, but it was the power of the great trust behind the pricefixing which was the cause of the hardship which it is vainly sought to remove by Section 2 of the Oldfield bill. And the way to remove both the commu ity's anxiety over price-fixing, and your anxiety over the effort to limit that right, is to suppress private monopolies and combine ions of like character.

Make clear the distinction between that

nonopolizing, which the Sherman law eeks to prevent and to extinguish, and that price-fixing which is an incident of the individual development of business and the busiding up of reputations of goods as of individuals—take up the work and the building up or reputations or goods as of individuals—take up the work of education on those lines, and you will, I am convinced, succeed and ultimately will get such wise legislation as Denmark has given to her people on this subject.

ber over and over again to the same lamp,
or by peasing it successively into the
luminous sone of several lamps. Besides,
the apparatus must be so constructed that
the water, while under the influence of
the light, is strired up so as to turn over
and over microscopic suspended matter
which might have escaped direction and
which might screen microbes from the
light.

A typical European starilizer is to be found in one of the suburbs of Rouse, France. For over two years this instaliation has supplied water starilized by ultra-violet rays. Since the introduction of the system not a single typhoid case has been known among the subscribers, whereas the percentage of typhoid cases in neighboring districts is appreciable. The most recent types of sterilizing approximation of the process of the system of the system

The most recent types of sterlitting apparatus are characterized chiefly by the fact that they use the light in a more ecnomical way than any apparatus hitherto constructed. The principles involved are such that the construction of very large sterlitting units is possible.

The apparatus consists of a tank or

ong canal through which the water flows Balle plates are interposed to stir up the water as it flows. Into the walls of this tank are inserted at intervals of severa feet, quartz tubes fitted water-tight to vertical plates constituting part of the walls of the sterilizing tank. These quartz tubes are about two inches in ulameter and eight inches long, and are closed at the end. The vertical plates are provided with external metal boxes which carry the lamp supports. The lamps are not unlike a pistol in shape and are characterised by a very narrow U-shaped luminthat it nearly file the two-inch quartz tubes. All the light produced by these "pistoi" lamps therefore enters the water hrough these quartz tubes, whereas th through these quarts them, whereas the lamp itself is protected from contact with the water by these same tubes. This is of importance, because the production of ultra-violet rays in quarts mercury vapor temperature of the tube (the iampe usually run at a temperature of about 800 deg. Cent.). It is, therefore, necessary to prevent the lamps from touching the water, which would cool them down to such an extent that the production of ultra-violet rays would be very low and

uneconomical. The sterilising canal is equipped with a maximum of tweive such lamps, each uning 1,800 watts. One of the installations has been running for eight months and sterlises the water in a municipal plant at the rate of 1,700,000 gallous per day. Most of the time only a few of the lamps are illuminated.

In larger water plants, several such canals may be operated in parallel. If the unit is small fewer lamp, even only a single one, may be employed and the sterllising tank reduced correspondingly in size. In the latter case the baffle plates must be so arranged that the water is led several times near the single source of labels.

The small apparatus illustrated in the accompanying engraving has been used for military work as a field starilizer. The complete equipment in this case, mounted on a run carriage, consists of a gasoline hactor generator set, water pump, fitter, and the ultra-riolet ray starilizer.

A similar outift has supplied water to a Said hospital during the French-Morocco campaign where it has been in containt use for nearly two years for supplying water for dithinks and surjects purposes. The respect by the sulgeon in charge states that these has been no case of hospital sixfection or typhoid during all this time, proving thereby the utility of this sterilling apparatus.

You don't buy your tobacco cheaper. You buy the <u>RIGHT AMOUNT</u> at a time.

TIN That simple idea has <u>SOLVED</u> the vexed problem of fresh tobacco in a handy pocket package.

Stag is something more than one of the world's finest tobaccos. Its FRAGRANCE is the most delightful thing in the whole history of smoking. No other tobacco has it, or can have it.

A single tin of Stag will show any smoker what he has been missing.

Sold only in 5 Cent tine and 90 Cent pound glass humidor jars.

\* EVER-LASTING-LY GOOD"

#### Coral Builders and the Bell System

In the depths of tropical seas the coral polyps are at work. They are nourished by the ocean, and they grow and multiply because they cannot help it.

Finally a coral island emerges from the ocean. It collects sand and seeds, until it becomes a fit home for birds, beasts and men.

In the same way the telephone system has grown, gradually at first, but steadily and irresistibly. It could not stop growing. To stop would mean disaster.

The Bell System, starting with a few scattered ex-

changes, was carried forward by an increasing public demand.

Each new connection disclosed a need for other new connections, and millions of dollars had to be poured into the business to provide the 7,500,000 telephones now connected.

And the end is not yet, for the growth of the Bell System is still irresistible, because the needs of the people will not be satisfied except by universal communication. The system is large because the country is large.

An Automatic Electric Light Plant position the exhaust valve is released and compression therefore occurs at the proper vals. The dynamo then ceases to act as a motor. As the speed rises the mo commences to take up the load and to put current into the battery. If, however, the load is light, say, a load of two or three lamps, the engine is not started when the lamp switches are closed, for the current needed for such a load car easily be supplied by the battery. ch a small current is passing through the coll A of the relay, the magnetism pro duced is sufficient to draw the contact C downward, and consequently the engine remains at rest. But after these two or three lamps have been burning for a cer tain period the voltage of the battery naturally begins to fail, and ultimately the mre at the terminals attains a value ers further discharge undesir-At this point it is nece the engine to be started. To enable this to occur the relay is also fitted with a simple coil B, which is connected across the terminals of the battery. Obvious as the voltage of the battery falls the agnetism produced by this shunt coll lminishes. When this occurs the spring on the left of the relay lifts the shunt magnet so that the lower contact ris and touches the contact above it. This also causes current from the battery to be supplied to the dynamo, when the latter acts as a motor. The engine is then run up to speed and charging takes place in the manner already described. It will be seen that the plant is absolutely automatic in action and the engine is started and stopped according to the demand for the load and the condition of the battery. There is one trouble which might arise if engine were allowed to run short of gasoline or if the ignition system failed to operate. Clearly under these conditions the plant might be driven by the battery until the cells were exhausted, this havng anything but a beneficial effect upon

#### only enhanced in the manner described, but also cuts off the current in the event of the plant's being overloaded The Current Supplement

IN this week's beare of our Suprements I. R. T. Mohas writes on the scientific advancement of the canning industry.—A. H. Brown describes an automatic astronomical calculator, which replaces long and tedious tebular computations by simple automatic mechanical operations.—It is well known that the manufacture of white lead is fraught with danger to the health of the workmen. A sanitury system of handling white lead is described and illustrated—A very important article appearing in this issue is a discussion of "The Principles of Fuel Oil Engines," by Ford C. F. Hirschfeld.—Il. Passavant writes on the uses of artificial insulating materials in the construction of electrical apparatus.—G. Gilmour contributes an article on Safety Engineering.—Another subject dealt with is the mechanical design of switches.—The average cost of killing a man in war is \$15,000. Contrast with this the cost of saving a hunan life by strict attention to sanitary requirements in the cansi sone: \$2.43. This is one of the points brought out in an article on Life Preservation.

#### A Method to Prevent Tarnishing of Silver

A SIMPLE and admirable method of values while not in use in suggested by La Revue de Châmde Industrielle. It consists in rubbing the articles with shooth in which a little collodion has been dissolved. A very delicate protective him is thus formed on the surface. This fifth is easily removed by weaking with warm water when the ebject is again required.

McN. writes;

## Lost power means worn metal

"X" indicates the motor where your power develops. But:

A great deal of the power developed in combustion chambers never gets to the rear axles.

Most of the power lost on the way is taken up by friction.

If motorists understood better the costly results of unnecessary friction they would select their lubricating oil with the greatest care.

Only oil of the very highest lubricating sailty can properly protect the moving parts.

Only oil whose "body," or thickness, is suited to your feed system can properly reach the friction points

Correct "body" is quite as important as correct quality.

And correct "body" cannot be deter-mined by guess.

Motor-constructions differ widely. Be-fore the correct "body" for your feed re-quirements can be delermined, the con-struction of your motor must be known and carefully considered.

To this end, every year we analyze the motor-construction of each of the season's models. Guided by this analysis and by practical experience we determine the correct grade of (argoyle Mobiloil for each make of car

The correct oil for each car we then specify in a lubricating chart (printed, in part, on the right)

part, on the right)

The oils specified have extraordinate warming qualities and will retain an efficient lubricating "body" under the most suits the feed requirements of each car they are recommended for

The lubricating chart in this page represents the professional advice of a company whose authority on scientific lubrication is unquestioned the world over The Vacuum Oil Company

If you use oil of lower lubricating qual-ity or of less-correct "body" than that specified for your car, your motor must face loss of potwer, unnecessary friction, and ultimate serious damage

In buying Gargoyle Mobiloti from dealers it is safest to order either a full barrel, half-barrel, or a sealed five-gallon or one-gallon can.

See the name and our red Gargoyle on the container

A booklet, containing our complete lu-bricating chart and points on hibrication, will be mailed you on request

### **Trade Marks**

#### **Trade Names**

Do you use a Trade Mark?
Do you own the Trade Marks you use?

You should read this booklet to obtain a definite and clear conception of Trade Mark rights

TRADE MARK is a most valuable business asset. It will pay you to know how such marks are made valuable, and why and how they are protected. The registration of trade marks is explained in this booklet, which gives a thoroughly comprehensive idea of the requirements for registration. The elements of a good trade mark are fully discussed, and many tests to determine the requisites of a desirable trade mark are given,

The booklet is printed in two colors and is illustrated by fifty engravings

## SCIENTIFIC AMERICAN HANDBOOK OF TRAVEL

With Hints for the Ocean Voyage for European Tours and a Practical Guide to London and Paris

By ALBERT A. HOPKINS, Editor of Scientific American Reference Book

At last the ideal guide, the result of twenty years of study and travel, is completed. It is endorsed by every steam-ship and railroad company in Europe. To those who are not planning a trip it is equally informing. Send for illustrated circular containing one hundred questions out of 2,500 this book will answer. It is mailed free and will give some kind of an idea of the contents of this unique book, which should be in the hands of all readers of the Scientific American. It tells you exactly what you wish to know about a trip aboad and the ocean voyage.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

#### Should the Government Manufacture Its Own Armor Plate?

LITHOUGH there may be some division of opin ion as to the wisdom of certain of the policies of the present indefatigable Secretary of the Navy, one, surely, will deny that Mr. Danlels, during the w months he has been in office, has given every evidence of a sincere purpose to promote the interest of the Navy by the use of every means at his command; and if that conviction should become fruly settled in and it that converted should become many section in the minds of the people of this country and their repre-sentatives in Congress, Mr. Daniels will be in a fair way to secure many of the betterments of conditions at is aiming. One of the most important innova tions which he has suggested is that of the construction by the Federal Government of an armor-making plant of afficient capacity to enable the Government to supply fifty per cent of the total amount of armor plate re ed annually for the construction of warships.

There was a time when the SCIENTIFIC AMERICAN would have strongly opposed any such suggestion, on the ground that previous experience had shown work of this character to be more tellous and more costly then similar work when done by the private contractor. But with the lapse of time conditions have changed, and the results obtained in Government manufacturing plants, particularly during the past decade, have shown superior product cau be ment shops and yards, which, if the labor restrictions are considered, compares favorably with the cost of contract work. Results obtained in the construction of the battleship "New York" prove that the above broad statement is true, even in the case of warships that are hullt at navy yards. The "New York" was built within the limits of the appropriation, and the navy yard bld came within a negligible amount of the bid put in by the private yards. In this comtion it should be noted that the work on such ships is of the very highest character, fully equal to similar work in private yards; and there is always the great advantage to the may yards to maintain a large and thoroughly-drilled force, which understands the peculiar work of the pards, and is always available should a

sudden emergency of war arise

The wisdom of the construction of a Federal armor plant will be settled if a satisfactory answer can be given to two questions. First, could a Government plant when built organized and by thorough working condition, turn out a product equal to that now de livered by the private maker? Second, could it deliver this product at the same or n less price than is now paid by the Government? In answer to the first question it is sufficient, surely, to point to the exceedingly fine paval gun shop at Washington, where a large part of the armament for our warships is built, the o of which is believed to be as tine as that delivere any gun shop. Government or private, the world over or to the excellent product of our navel powder factory. It is stated by the Bureau of Ordnauce of the Navyvery good reason—that the Government output of guns is equal in quality to that of any gun makers, and that our gowder, so far as comparisons can be made, is decidedly superior in alt-round efficiency to any other

As to the question of cost, the Secretary of the Navy

has informed the Senate that a plant capable of turning out ten thousand tons of armor plate a year, or about half of the armor needed on a two-battleship programme, would be \$8,456,000, and that when this plant was in running order, armor could be delivered at a cost of \$314 a ton. The price now paid is \$454; so that if the Chief of the Bureau of Ordnance who supplied the figures is correct, and there is every re to believe that he is, a saving of \$140 a ton would be to conseve that he ha, a saving or \$130 a ton wound or effected over the present price. This would represent a saving to the Government on ten thousand tons of \$1,400,000 annually. After deducting four per cent interest on the investment in the plant, there would still the price of the present of the investment in the plant, there would still the price of the present on the investment in the plant, there would still the price of the present on the investment in the plant, there would still the price of the present of the pres remain a net saving to the Government per year of over

A review of the facts, then, seems to justify the enate and Congress in voting the necessary appropristion for the construction of such a plant.

E offer no apology for referring editorially in two successive issues of this tonnection. ▼ ■ the question of oil fuel. Last week we indi-cated some of the serious contingencies which might arise if the Navy made a sweeping change from coal to oil fuel. The question is of national importance; for anything that vitally affects the Navy is of vital importunce to the peace and permanence of the nation.

this age of rapid development it not infrequently happens that the progress of invention, with a positivemappens that the progress of inventions, with a positive by startling stride, will give to one of the natural products a position of commanding importance never dreamed of until the fruitful inventor opened up new and wider fields of usefulness. The latest, if not the most conspicuous instance of such a development is to most conspicuous instance of such a development is to be found in the case of perfolem. Formerly valued almost exclusively as a source of light, its field of us-fulness has been rapidly widened by the advent of the laternal combustion engine, the automobile, the motorboat, the suxiliary cruiser, and the seroplane and the dirigible. Concurrently with this rapid widening out of its field, there was started and carried to a successful demonstration that elaborate series of gations and luventions which have given us the perfected oil burner and the successful use of oil as a fuel for steam generation.

The result of this widespread extension of the use

oleum has been to give to this natural product a position of commanding importance, both to the na-tion and to the individual. We pointed out last week how seriously our national interests were or might be affected by the availability and cost of this fuel, and arected by the availability and cost of this fuel, and we wish now to suphasize the fact that the progress of invention has made the same questions of availability and cost of very intimate importance to the health and pleasure of the individual citizen.

By way of emphasis, it is sufficient to instance the utomobile and its humbler brother, the motorcycle. The past three or four years, thanks mainly to the skill of the automobile and motorcycle manufacturer, have seen a wide extension of the previously comparanarrow circle which include able to bear the cost of purchase and ownership. cost of the fuel, which has been so steady and has a sumed such proportions as to discourage many people limited means who had hoped to become owners of their own machines.

view of the above facts, the petrol note with much gratification that the United States Department of Agriculture has called a meeting in Pittsburgh, on August 1st, to which a score of diff eut societies have been invited to send delegates, and that the gathering will devote its attention mainly to the question of petroleum and its various by-products.

The movement is being promoted by Irving C. Allen,
the expert on petroleum of the Bureau of Mines, who has given the following statem nt on the object of his

"A study of petroleum and its products has never ughly or comprehensively made within the United States.

"Sluce each year crude petroleum and gases are produced in the United States, having a value in excess of \$200,000,000, it is most important that a thorough study of these materials be undertaken.

study of these materians be unsertanen.

"This study should include the origin, geology, statistics, drilling methods, transportation and uses of crude periodeum, and a critical and extentife description of petroleum products of all kinds, including bitumen and gases

The proposed technical hody will work in co tion with the International Petroleum Commission, organized in Paris as far back as the year 1990. This on on the part of the Bureau of Mines should receive the whole-hearted co-operation of everyone who is interested in the petroleum question, and particu-larly of the powerful manufacturing corporations which directly or indirectly are dependent upon the petroleum ludnstry.

The Grade-creating Buneau

HITHER familiarity three, comment
desprey no. 1; to contain a side of the contain and indifference to the dealth and familiar as result from once of the needless adaptes in a chief public be exposed. Unbeyrily, us only or, us over your and to find clear, proof of the centre of the mainty pertia which take their large annual to the centre of the mainty pertia which take their large annual three three contains the central transmission. numan life, there are certainly few which are more of human life ventable than the grade-crossings of railroads. a century or so ago, when capital was scarce population more thinly spread over the land, it would have been idacing an intolerable burden upon the railroads to demand there should be no crossings public highways at grade level. Practically as cities, were built at street or highway level. The necessities of the case made such construction com-pulsory. But with the times conditions have changed. The better managed (or shall we say the more humani-tarian?) of our railroads have of their own volition abolished the grade crossings, or are now engaged in doing so. From motives of convenience and cost of operation alone, the average railroad manager would gladly abolish every grade crossing from the system. Looked at from his standpoint, grade crossings are a cause of delay and expense, to say nothing of mental strain they entail upon the engineman and the perpetual anxiety to the management; while leaving humanitarian considerations out of the question, there are the legal costs of compensation in case of accident and the always-dreaded notoriety and unpopularity which follow a grade-crossing accident.

So far as the railroads are concerned, undoubtedly the chief chatacle to the removal of grade crossings has the chief constants to the removal or grace crossings has been the expense of the reconstruction; but of late years it has come to be recognized that the cost of elim-ination should be considered as a joint obligation on the railroad, the State, and the municipality in which the crossing exists. It is under such an arrange that Chairman McCail of the Public Service Com sion has made an appeal, which we trust will re-ceive the favorable consideration of Governor Sulser. asking that the State appropriate \$1,000,000 as its share toward eliminating railroad grade-crossings in thickly-settled suburbs of New York city.

The appeal of the Commission is accompanied by an illuminating report upon present conditions, in which it is stated that on the Long Island Railroad system glone, there are 607 crossings at grade, of which less than haif, we learn to our autonishment, are protected by gates, flagmen or even alarm bells. In greater New York alame there are 477 grade-crossings which are designated as daugerous. It is noted that in Brookly between Norwood Arenue and Jamaica there are from 210 to 322 train movements, daily, over the crossings at each street, and that at one of the at each street, and that at one of these an average of 423 school children cross the tracks four times each Again, an investigation of Railroad Avenue in Brooklyn showed that in an hour and a half 453 persons went over a crossing, over which 11 local trains and 25 express trains passed during the same period and 25 express trains passed during the same period. In the four years, 1908 to 1912, 100 persons were killed at crossings within the limits of New York, and 150 were injured.

distribution of the cost of abolishing grade ings in this city is that one fourth is borne by the State, one fourth by the municipality, and one half by the railroad companies concerned. The companies as themselves as ready to proceed, and the city iso granted its share. The question of the removal of grade-crossings, and the abolition of conditions that are a disgrace to our civilization, is thus squarely in the hands of the Chief Executive, to whom the raitroads and the citizens of New York are looking for immediate and decisive action.

The Tenth International Geographical Congres

FTER being postponed for a year and a half, the tenth international geographical congress, which met in Rome this spiring, was occupied especially with discussing the international map of the world and polar exploration. Under the former head it was an unced that nine countries (including the United States) had undertaken the preparation of sheets of the international map in accordance with the pro-gramme drawn up at London in 1909. It is now preposed to hold another internation sed to hold another international conference, by in Paris, to settle several details of the un ably in Paris, to settle several details of the under-taking. The International Polar Commission had a secting in conjunction with that of the compress, and many chilment polar explorers and antibucines were in accordance, including Pary, Cagat, Brayan, Monden-abilid. Jeculute, and Stotingson, Greek fahrenet vers shown in the Canadian Argue seposition, suider Shattis-son. A proposal to not dispusable to the publical the grange of the Congresses laid for 4 hirsyl. Signeration, as-minated only by the object of the Sanstiana to Sander upon their own inargues if the Sanstiana the Sander upon their own inargues if the Sanstiana the Sander

Manufacture The Secretary of the Market at the spinion that by the disposal of buildings of dutheling are dutheling as the property of the standard standard water, and by conservative appropriation of entering the affects to persuade Campriss to live up to the wee-basicalipe-a-year programs while in the minimum necessary to keep our navy up to a reasonable strength for its duties.

awy; up to a resonance screenin for its duties.

"Min Sepfects a Datah Eurentian.—A correspondent in Holland draws our attention to the fact that the construction in that country of a feating dock of 14,000 tens, for Sovenbaya harbor is the Dutch india, should remind us that the feating drydook is a Dutch invesion, and that many feating docks of this type are built so Dutch ways and towed to their destination. Drydook towing is a specialty, and many foreign-built docks are towed to their destination by Dutch

Sues Casel Traffic.—During the year 1912, 20,275,-120 tone of shipping passed through the Sues Canal, an increase of nearly 2,000,000 tone over the year of as increase of nearly 2,000,000 tons over the year of 1811. The total receipts of \$27,800,000 were the greatent in the history of the casal. During the year 5,373 ships passed through the casal, and of these 3,383 few the British fag. Such figures as these yie ground for the hope that the Panama Casal may become addenuporting and even profitable sooner than some of our statisticians have predicted.

Our Latest Battlestig.—No. 39, the latest battlestig to be built for the U. S. Navy, is about to be laid down at the New York navy yard, Brooklyn. Sister to the "Pennsylvania," she will be the largest and most power-th battleship under construction. The particulars are: Largth, 608 feet; beam, 97 feet; displacement on rail, 31,400 nos. She will have a 14-inch bett, and 18 inches on the, turrets, in which will be carried twelve 14-inch, 45-caliber gun. The complement will num-ber 1,100 officers and men, and the ship will cost, com-Our Latest Battleship .- No. 39, the latest battleship plete, \$16,000,000.

The Engineer-Architect in Ancient Rome.—It was largely their development of the dome and the arched roof in masonry, that enable the Romans to build on a scule of daring and magnificence which has not been ampramed in our modern age of steel. Rosent accurations in Noro's palace have revealed five universances. tions in Nerv's palace have revealed five subterranean vaulted rooms in the proximity of the diffing-room, which were built as fish tanks and used to keep fish alive for the use of the imperial table. The vault and the dome or round roof of the Romans served the purpose of the modern I-beau and latticed roof girder as used by the present-day architect and engineer.

as used by the present-day accusions one engineer.

Progress in Electrifying Steam Railroads—If we beer in mind the many difficult problems and the great too involved in changing from steam to electric operation or railroads, it must be admitted that this country has made great strides in this direction. A recent estimate places the total number of miles of single track that has been obsained from steam to algorith constition. inst has been changed from steam to electric operation at about 1,000 miles, and the same authority finds that approximately 1,500 miles of single railroad track will probably, during the next few years, be subjected to the same change. Too much oredit cannot be given to the New York Central and the New Haven railroads for the ournapous pioneer work which they undertook in this direction. that has been changed from steam to electric operation

Completion of a Great Hydro-Electric Plant-the completion by the Mexican Light and Power the completion by the Mexican Light and Power Company of its light and power plants in Mexico, another great hydro-electife work is about to be put in service. The main power plants have an aggregate capacity of 127,000 horse-power and auxiliary plants at four-sepa-rate points bring up the total horse-power to about 150,000. The work includes large storage reservoirs in the mountains, tunnels through the intervening ridges of rock and transmission lines. The aggregate ridges of rock and transmission ince. The aggregate storage capacity is sufficient to keep the plants in opera-tion for six months without any rainfall. The current will furnish light and gower for the city of Mexico and its capacity is sufficient also to run the trolley systems in the city and the whole Federal district.

and its capacity is entroisent also for in the county systems in the city and the whole Pederal district.

Sees Ties in Europe.—During a recent visit to Europe, the writer was struck with the fact that the steel tie, which has made very little handway in the United States, is extensively used abroad, and particularly in Germanny, where only two years ago the Presiden State Radiways alone purchased over 150,000 tons of ties of this character. We steed on the fine streeted of road between Berlin steel Stamburg, that the steel-tie track was of most receding to the structure and higgmenous; and we were particularly surprised to fluid, their ownersery to the general impression, the bandways and alignment; but was not maken the bandways and analog but were not maken the structure and higher most most structure, but were not more structured to fluid. Their ownersery to the general impression, the bandways and maken the structure and the structure and higher structure of facts more structure of facts and the structure and the stru

Transatiantic Wireless Communication from Say-ville, Long Island, to Berlin, Germany, has just been established by the German Telefunken System. Messages sent from Sayville on July 12th were clearly received at the Nauen station near Berlin, spanning a distance of 4,000 miles.

Electrolytic Protection Against Boller Corrosion

Silectrigitic Protection Against Boller Corrosion.—
A method of preventing boiler corrosion has recently been developed in which iron anodes are introduced into the boller, and currents are passed from them to the metal parts of the boller. Iron is used for the anodes because it is cheap and because the salk of the anodes because it is cheap and because the salk of the property o negative pole and consequently hydrogen is given off, due to the electrolytic action. This prevents any scale or dirt from forming on the tubes or shell and loosens any adhering foreign matter that may have lodged there prior to the application of the current.

Electric Power Developments in Russia.—It is re-orted that the Russian government has lately granted the rights to English interests for the constr cale riguts to Engine interests for the construction or cleetric stations, using the power of Terek River and Lake Goktoha, together with long power lines running to distant points. First, a temporary plant will be erected on the Terek River near Gvilete village, which rnish 20,000 horse-power, then a permane turbine station on the same stream near the railroad station of Lars, so as to source as much as 50,000 horse-power. Current from these plants will be taken over power lines to Tiflis and Vladikavkas. One or two ulic plants will also be erected on Lake Gokt near the Tarstoha and Akstafa rivers, and these are expected to provide at least 40,000 horse-power. Current will be used in the city of Tiflis. It will be seen that the present project is quite an extensive one

the present project is quite an extensive one
Davice for Detecting Fire Damp. An electric
device which is said to give very good results in
Australian mines for detecting fire damp and marging
an alarm hell, is based on the use of is porous vessel
into which the gas penetrates. The apparatus has a
U-tube containing mercury in the lower part. On one
side is a platinum wire which always remains in contact
with the mercury, while the second branch of the tube
has a platinum point bying above the level of the mercury. Current from the battery and bell comes to the
two platinum points. On the first branch of the tube is
placed a closed, porous vessel, and if there is fire damp
at this soot, the gas posertsets the porous oup and acts at this spot, the gas posetrates the porous cup and ant to horresse the pressure on that side, thus driving down the moroury and causing it to rise in the other branch so as to complete the battery circuit and ring the bell. The contact point is adjusted so that a sufficient proportion of fire damp in the air osuses the moreury to rise to the proper height for making the contact.

Goldschmidt Transatlantic Wireless Exper Goldschmidt Transatiantic Wireless Experiments... The daily papers recently contained reports of wire-less telegraph communications between Neustadt, near Hanover, Germany, and Tuckerton, New Jersey, established under the Goldschmidt system. The re-ports have not been absolutely authenticated. One ports have not been amounted authenticated. One of the principal features of the system is a high fre-quency generator invented by Dr. R. Goldschmidt, which will give 150 kilowatts at a frequency of fifty or sixty thousand oscillations per second. The machine consists of a rotor and stator arranged to give 15,000 consists of a rotor and stator arranged to give 15,000 evolutions per minute. This high frequency current is returned to the stator, producing a rotating field opposite in direction to the rotation of the rotor, thereby producing a frequency of 80,000. This in turn is sent back through the stator, so that it yields 45,000. In this way the frequency may be stepped up to 50,000 oscillations. At the receiving station a fine insuisal note is heard which is readily distinguishable from other signals. The Goldschmidt machine is known as the "singing wheel."

An Electrical Besearch Laberatory and Bureau is to e established at the Massachusetts Institute of Tech-ology. In connection with the laboratory there is nology. In connection with the laboratory more mology. In connection with the laboratory which an endowment of over \$110,000 is assured. Dr. Harold Pender will be the director of the laboratory with H. F. Thomson his moretary and sesistant. The new laboratory as his secretary and assistant. The new laboratory has received an endowment of \$10,000 a year for five years from the American Telephone and Telegraph Company, and \$5,000 a year for five years from an anonymous donor, the latter to be used in determining the distance to which a street car passenger can, with reasonable profit, be carried for a five-cent fare. The laboratory has also received a gift of \$2,000 from the Boston & Maine and the New York, New Havon & Hartford Railroad, for the study of freight handling at ternainels. About a year ago the American Telephone and Telephone a

Aerological Observations in Brazil.—Prof. Berson of the Undenberg Observatory recently made a journey to northeastern Brazil to arrange for carrying out a series of upper-air observations in that region, which lies in the zone of the southeast trade-winds.

are ratural filistory Collections of Capt. Scott's Expedition are to be turned over to the Natural History Museum, South Kensington (t. e., the natural history branch of the British Museum). The trustees of the British Museum have agreed to undertake the publication of the natural history results of the expedition.

The German Antarctic Expedition under Lieut. Filchner will not resume operations next season, as had been intended. The Geographische Zeitschrift anounes that the expedition's ship, the 'Deutschland,' is about to return to Germany, marking the end of an enterprise which aroused much patriotic enthusiasm it was undertaken (before the attainment of the pole by Amundsen and Scott), but which has been omewhat disappointing in its results

The Meteorological Service of Russia finds itself in ition, rare in the experience of European scie tific institutions, of having ample funds for its present needs and future development, thanks to a very liberal mcrease in its budget recently authorized by the gov-The buildings of the Central Physical servation, the headquarters of the service in St. Peters-burg, are to be enlarged; a meteorological observatory is to be established immediately at Vladivostok, under which will be organized a network of new Siberian stations; a new aerological observatory is to be erected this year near Paylovsk, and in 1915 serological sections will be added to the observatories at Tiflis, Ekaterinburg and Irkutsk.

Aeronautical Meteorology in France,-The presi of the Meteorological Society of France, Leut.-Col. Rénard, who is more widely known as an aeronaut than as a meteorologist, has addressed a circular letter to the principal meteorological and aeronautical societies and the official meteorological institutes inviting ties and the official meteorological institutes inviting them to send delegates to a conference on the subject of aeronautical meteorology; its objects being to facilitate the utilization by aeronants of the daily weather forecasts and other practical work of meteorologists, and, on the other hand, to encourage aeronauts to make scientific observations during their ascents for the benefit of meteorology.

Papain, the most important chemical constituent of the papays, is the subject of a recent report by the American consul at Colombo, Caylou. Probably few of the travelers in tropical countries who enjoy the melon-like papaya realize that this fruit contains one of the most valuable digestives known to medicine, though the natives of the Orient, especially in southern though the natives of the Orient, especially in southers India and Ceylon, use the fruit almost unversally to prevent dyapopsia. There are several varieties of Caraca papea, and the papain obtained from the different kinds varies accordingly, the best being that derived from the male trees of a shybrid variety occur-ring m Ceylon. The digestive and disintegrating proocoks in Ceylon wrap tough meat in fresh papaya leaves to make it tender, or apply a small quantity leaves to make it tender, or apply a small quantity of the milky juice of the plant to the surface of the meat, or put a piece of the green fruit into the raw curry when the meat will not boil soft. Papain is said to be capable of diseasing ten to twelve times its weight of egg albumen at the temperature of the human body.

The Sounds of Earthquakes, as illustrated in the seismological records of Great Britain, are the subject of an exhaustive memoir by Charles Davison in Besor an exhaustive memoir by Charles Davison in Det-trige zur Geophysik. These sounds are described as variations of heavy rumbling noise, so low in pitch as almost to be more felt than heard (in many cases inaudible to persons who are deaf to very low tones), and belonging to one or another of the following types The passing of wagons, thunder, wind, the fall of a load of stones, the fall of a heavy body, an oxplosion, or some other miscellaneous sound. The oxplosion, or some other miscellaneous sound. shock is felt, in place and time, are particularly intersnock is rett, in piace and time, are particularly inter-esting and significant. In strong earthquakes the sound area occupies a central region (on an average two thirds) of the disturbed region; in moderate earth-quakes the two areas are approximately of the same magnitude; while in many slight earthquakes the sound area is larger than the disturbed area. As a rule the beginning of the sound precedes the shock, and the end of the sound follows the end of the shock. Assuming earthquakes to be caused generally by the slips which constitute the growth of faults, the author points out that the seismic focus in its simplest form must consist of a central region, from which the shook vibrations chiefly come, surrounded, at any rate above and interally, by a marginal region, from which the

## The Salvage and Repair of the Steamship "Royal George"

Converting a Sunken Ship Into a Bubble of Air

By R. G. Skerrett

The reloating and the repair of the stranded steamlet the "Royal George" gives us a strikingly novel example of what compressed air has made possible when skilfully adapted to the needs of a case. This

particular exploit, too, shows the sandhog in a new field of activity—not the tunnel and calsson work with which we have some familiarity.

While outward bound from Montreal for Bristol, the liner "Rayal George," during a dense fog, wont ashore at high tide about aline miles below Quebec. That was upon the Bih of bust November. The ship is a craft of 14,000 tons, had cargo and passengers aboard, and was upon her last homeward trip hefore whiter closed the NI Las rouse to mivigation. At once, local salvage facilities were hastened to the secue and every ordinary effort promptly directed toward the vessel's refunctive.

After nearly two weeks of fruitless striving, it was recognized that the usual salvage procedure and apparatus would use assert, and Mr W. W Woherspoon was sunnound from a nearby wreck upon which he was time canaced—the stranded collier "Gladefone". I'pon the latter he was using compressed alt, and the un derwitlers decided to try the same method upon the "Boyal George," authorizing Mr. Wotherspoon to go ahead. Accordingly, all of the pumps were removed and the hatches to the lamaged compertments soaled by alt-tight plates. All locks were secured to the circular passageway in these metallic intic covers, and concertains also made by high between the air compressors and the lapture holds. In three days tills work was completed and the compressors started at 10 P. M. of November 22nd; iffects minutes here the forward errap space was dry!. It is the retreating to know how this was accommissed.

If was necessary to provide against the pressure of a head of water of twenty-three feet that the compressed air was to offset, and the deek overlying the comparison was not equal to a bared ing stress of this magnitude. Worse will, that deek did not rest upon a solid sile; that deek did not rest upon a solid sile; that deek did not rest upon a solid sele deek, and there was the certain risk of blowing out the calking between the lanks, which would mean failure. To meet the struction, Mr Worterspoon poured not pitch into all the deek seems, covered the deek with a number of layers of far paper, and over these placed a vener of sprace flowing. Then he braced the pressure deek, let us say, by shores reaching to the deek setow, and in this fashion distributed the stress to be absorbed when the holds should be filled with compressed air. In hrief, he turned the dooded cargo spaces into calesons, and then all was hi readiness for the expulsion of the invading water

An internal examination of the injured holds showed that men'r Jorty per cent of the ship's bettom was damaged, but it also demonstrated that the alr-salvage apparatus was equal to the demands to be placed upon it. The next afternoon, two hours before high tide, the water was blown out from the flauded compartments and the vessel floated clear. But this was not the solution of the entire problem.

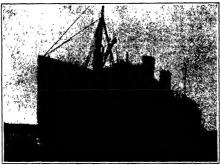

The neutron dry-dock was at Montreal,

The nearest dry-dock was at Montreal, Snowing : 140 miles away, and the river's closed season was drawing near. But, besides this danger of

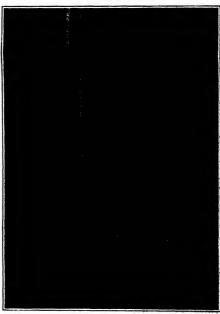

season was drawing near. But, besides this danger of having the ship held for mounts, there was the prospect of heavy dock charges independently of the cost of repairs. There was every reason for haste and economy within reason, but the question was "How could the 'thoyal George' be made ready for see otherwise?" Mr Wotherspoon answered this in a unique and a thoroughly satisfactory mauner. This is the best part of the story.

The ship was anchored out in deep water, and down into the damaged spaces the sand-hogs were sent

through the air-locks—the compartments being held substantially drained by reason of the compressed air within them. Beginning at the uppermost point of the wounds in the ship's steel skin, the sand-logs roughly

The steamship "Royal George" on the rocks in the St. Lawrence River.

Showing how the "Royal George" was salved and repaired without dry-decking.

scaled these openings by covering them with heavy planking calked with mid and caken: the water further receding as the "pude-boards" reached downward and finally covered the openings. So far, so good, but this scaling was but temporary and effective only so long as the afr pressure was mishbathed. Before, the vessel could proceed seaward it would be accessary to cover the damaged bottom from without with sizes plates made water-tight. Blocking, the kines with "podge-boards" wotild seem to have smale this important of the state of the sizes of the state of the state of the state of the sizes with "podge-boards" wotild seem to have smale this important

sible, but there was a way to start the search regions From within, festible templates of word wars made to each needed patch, and upon these wars made to places for bot holes—the same positions being and

cated upon the toner surface of the sealer plating. The templates we small he through the air-locks and guided the similar workers in forming the steel particular size in boring the threaded both theirs. Their these holes trap both were careswall. In the meantime, neightly league, holes were drilled around each wound and sander depit with wooden plans from within. As weighted ladder was awang under the ship and directly beneath the rents to be manded. A diver was sent down what took his place upon-this submerged platform for the purposes of co-operating with the small-hogs within the ship.

When each patch was ready, with its

When each patch was ready, with let tap botts in Jince, it was nowed down to the diver, who merely directed it into peation, the me inside withdrawing the wooden pinns so that the holts could enter their proper holes. Then nuts and washers, with plenty of red lead, were piaced upon the bolts and screwed well kome in order to nake the patch-plate song and water-tight. With this done, the "pudge-boards" were removed and the raged edges of the damaged hull cut away by means of Oyz-acceyiene fames. In this mauner all of the repairs were effected, and the total damage covered an area of 700 square feet.

The "Royal George" left the St. Law-

The "Royal George" left the St. Lawrence for halfars, and on the way emcountered heavy weather at sies, but Mr. Wotherspoon's repairs proved quite equal to the stresses placed upon them. At Halffar, because of the povelty of the work and to satisfy the insurance people, the liner was docked for a brife casmins tion. Everything being found in specified shape, the "Royal George" loaded with cargo and returned to England without further mishap.

#### America's First Safety Exposition

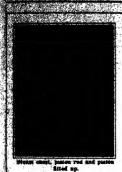

THE First international Exposition of Astrety and Sanitation ever held in America will take piace in New York etty. December 11th to 20th, 1933, under the asuptices of the American Minesum of Safety. Safety and besith in every branch of American Industrial life, naunfacturing, trade, transportation on land and sea, business, confineering, in all of their subdivisions will be represented at this exposition. It will be the first step toward making a representative exhibition of the progress of safety and preventive methods in America.

There will be absolutely no limit to the scope of the exposition. It will embrace, everything devoted to safety, health, smittation, accident prevention, welfare and the advancement of the science of industry.

By a special act of Coogress, exhibits from Europe and other forwign countries are to be admitted feet of duty. European employees have cut their accident and death rate in half by a persistent campaign for safety. There are towasty-continuous of safety in Europe. All of these various nuscenns will contribute be the American exposition.

the American exposition.

In the United States every year 40,000 workput are killed, and 3,000,000 are injused, while 4, 000,000 are injused, while 5, 000,000 are in from preventable causes. A coherentire sections of the water was earlier capacity of the last for one year is from tunded intillin deligner. ### Simple Methods in Modelmaking

How Soft Wood and Cardboard Can be Used

By Percy Collins

It often happens that an inventor cannot afford to have his ideas embodied in a working model by a professional model-maker. How one may make his over model, with solveors and paste, out of such materials as come to hand, is here The methods are capable of many modifications to suit a variety of The machines need not necessarily be very durable, so long as they can be made to operate and demonstrate the correctness of the inventor's theory, or espose serious faults that may be overcome before the patent is applied for .-

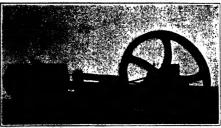

PREED object of this paper is to place before inventors A and others who may be interested, the result of certain experiments in model-making which have been made with cardboard, soft wood and other easily obmined and sadly worked materials. The construction of a model of machinery by the ordinary methods—the various parts being turned or cast in metal—is a lab-ons and often a costly undertaking. This fact is well known that the inventor frequently

hesitates to put his ideas to the prelimin ary test of a model, simply because the outlay which would be involved is beyond his means. Of course many inventors make their own models; but there are ers who cannot do this because they mary practical experie metal work. To these latter the following paragraphs are chiefly addressed. The writer has found, from experience, that many kinds of mechanical movements can be effectively illustrated by means of els made from simple materials that can be obtained practically without exe, and that can be cut and shaped with a sharp knife, a pair of scissors, a die and a sheet of fine glass-paper. The simple methods adopted can be best

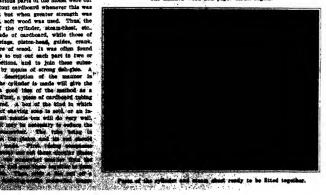

explained by reference to the accompaning photographs which show the model of with the most important details of its coninally made in order to teach some chilthe names of its several parts, was built up entirely from scraps of wood, card-board and pieces of steel knitting-needles. The only exception was the fly-wheel. This (it was an ordinary cast-iron wheel) was purchased at a general store, the co being ten cents. The foundation of the engine was simply an oblong wooden box, in the lid of which two holes were cutone for the fiy-wheel, the other represent-ing the crank-pit. When these holes had been cut out, the lid of the box was screwed permanently into place.

The various parts of the model were cut out in stout cardboard whenever this was feasible; but when greater strength was required, soft wood was used. Thus, the parts of the cylinder, steam-thest, etc., were made of cardboard, while those of the bearings, piston-head, guides, crank, etc., were of wood. It was often found desirable to our our seem part as more sections, and to join these subse-quently by means of strong delegate. A detailed description of the manner is which the ordinate is made will give the I the cylinder is made will give the of a good ties of the institut as a . Size, a good ties of the institut as a . Size, a good ties of carbonard typing spired. A box of the start in which for chartries made to sol, or as in-ments possible box will do year well, the firmer he companity to enter the properties. This tries partie is important. This tries partie is the properties. than the cylinder tube, and give it firmly in an upright position to the piston, using a small piece of cork for support. When the glue is dry, proceed to fit up the cylinder. Two square pieces of card will be required, in one of which a round hole has been bored for the play of the piston-rod. Put the piston rod through this hole, insert the piston into the cylinder, and glue down square cover. The other square of cardiourd should

Parts of the bearings, cross-head and guides.

The finished wood and paper model-engine.

when the glue is quite set, the overlap of both covers should be neatly (rimined away by means of scissors or a sharp knife Therenfler the bands can be glued round the cylinder, and the steam chest cut out and fitted lute place.

All these points are ittustrated in the pholographs

reproduced on this page. But it is mmecessary to de-scribe the whole of the work in detail, chiefly for the reason that the reader will be likely to modify the methods to suit his own convenience. Enough has been this own convenience. Enough has been written to render intelligible the manner in which a model of this kind can be made. One or two points, however, call for emphasis. It is a wise precaution to purchase the fly-wheel before work is com enced, the reason being that the size of the wheel will necessarily be our guide when we plot out the dimensions of the other parts. Once the size of the fly-wheel is known, it is a simple matter to determine the appropriate hore of the cyl-inder, stroke of piston, etc. When making When making the necessary holes in wood or cardboard. the best plan is to use a red-hot kulltingneedle slightly smaller as to size than the bole that we require. The glue used in model-making should be the strongest and best obtainable As to the fluishing of the work, it may be said that each part should be first rubbed down carefully with fine glass-paper, then conted with size, and finally rubbed down again. In this way all rough edges may be removed, and a uniformly smooth surface obtained. This remark will be found to apply as much to cardioard as to wood Lastly, the model should receive a cost of council, which will be found to lie evenly and well upon the sized surface

The full details of the slide-valve and eccentric genr were not attempted in the particular model shown in the photo-graphs. This model was intended to be driven by means of a small electric motor; and as it was to be used merely for oses of elementary Instruction, only sufficient details were reproduced to meel the particular ends in view. But it has been found that a working model cylinder, driven by compressed air, can quite easily be made from cardboard. It need scarcely be added, however, that the internal mechanism of the cylinder and steamchest must be constructed with great care The necessary accuracy metal-like surface may be imparted to the cardboard by rubbing all the fitetion surfaces with blacklend

The render who has followed carefully the instructions given above will find that he is able, after a little practice, to con struct models of many kinds of engines achines by using the simple mate rials which have been meultoned. It is quite possible to make a model factory, with every part of the equipment duly to scale, and all the machinery capable of being shown in motion. One may also e a working miniature of a machine whose movements are too complicated to be demonstrated on a drawing and prove or disprove his theories to his satisfaction.

#### Federal Regulations for Protection of Migratory Birds

THE Department of Agriculture amounces the selection of fifteen experts to advise the Secretary in randing regulations to make the new Federal protection of migratory birds effective. To these men, who will serve without commercian, will be referred certotic questions arising in connection with the tentative regulations occurity published by the Department in connection with the net of March 4th, which gives the Federal Government Jurisdiction over the migratory birds of the United Nation. The fifteen meselected, and who have already consented to assist in this adsbory equactly, are as follows:

John B Barnham, New York city, president of the American Game Protective and Propagation Associa-tion, chairman; F. W. Chambers, State Fish and Game unisdoner, Sait Lake City, Utah; Prof. L. L. Dyche State Fish and Game Warden, Prutt, Kuns.; W Finley, State Game Warden, Portland, Ore., E. H. For bash, State Graffhologist, Boston, Mass., Dr. George Bird Grinnell, New York, vice-president of the Boom and Creekett Club, and former editor of Forest and stream, Dr William T Hormday, New York, director of the New York Zoological Park, Hon. John F Larcy, Oskuloosa, lowa, author of the Larcy act regulating importation and interstate commerce in lifting and game; Marshall McLenn, New York, chalruna Committee on Conservation of Wild Life of the Camp-Fire Club of America, T Gilbert Pearson, New York secretary Nutlounl Association of Andubon Societies: Hon. George Shiras, 3rd, Washington, D. C., author of the original bill protecting migratory birds; Gen. John C. Speaks, chief warden, Columbus, Ohio; William P Taylor, Berkeley, Cal., chaleman Committee on Convation of Wild life in California; Hon. John H. Wallace. State Game and Fish Commissioner, Montgomery, Ala., Major Bluford Wilson, Springfield, Ili

The proposed regulations, in the that adoption of which and in the heurings on which these gentiemen will set in an advisory capacity to the Department, and which do not go hato effect before October 1st, 1913, are designed to secure the following results

1. Uniformity in protection of migratory game and insectivorous birds in the several States

2. Protection of birds in spring while en route to their nesting grounds and while muting

s. Uniformity in protection of migratury lidres at night.

4. Establishment of protected migration routes along three great rivers in the central United States 5. Complete protection for five years for the smaller

Complete protection for five years for the smaller share birds and other species which have become greatly reduced in numbers

6. Reduction of the open season on migratory game birds, but in most cases not more than 25 to 50 per cent

#### Saving Our Natural Gas

WILAT is believed to be a most notable demonstration of the conservation of the inherent resources of the country has just been accomplished by the United States Ilureau of Mines in the State of Okuhhema

A. J. Pullard of Bisker-field, Cultivaria, and A. J. Heggern of Pittsburgh, Pr., the two oll experts of the Bureau, acting under the direction of Dr. Joseph A. Holmes, have succeeded in stopping the waste of more than 150,000,000 embic feet of matural gas addity. This gas is worth \$37,500 for every day 11 is wasted and men'y \$13,000,000 in a year's time

When the Bureau's experts entered the field it is studied that 250,000,000 cubic feet of gas was being wasted, valued at about \$82,500, for every (wenty-four hours, or about \$23,000,000 a year. All of this will eventually be sweed.

The gas already saved is equivalent in heat value in a year's time to 1.875,000 tons of the heat coal, and before the advent of the Bureau's once Okhdonas was wasting fuel canal to 3.125,000 tons of coal.

The operators and dtillers after much skeptician inversion reacted the conclusion that the Federal experts' method of drilling is the proper one, and they are making preservations to stop the remainder of the waste of natural gas. The necessary apparatus is being an application of the property of the property of the natural property of the property of the property of the interior Equation 11 of the property of the property of the Burean's expects, in Okuhoma mutil more demonstrations can be given.

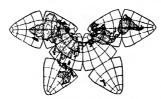

The Federal experts have successfully directed the drilling of two wells in which there would have been a combined waste of more than 20,000,000 cubic fact of natural gas daily under the old methods. They have succeeded in shutting off the gas in these webls and have drilled the well below the gas strain and into the oil. They may also directed the drilling of a number of other wells past the strain and without a waste of any of the gas.

The system to brief justine pumping of a mud-inden

finid into the well in such a mannior that it stops the gas from penetrating the well. In the past it is desired that in a great number of wells drilled in the Custling field in the gas some it has been found impossible to drill cuttrely through the gas formation, due to the pressure and volume of the gas. In a number of instances it has been necessary to shut down the well, and the money spent in drilling has been lost. Loss from this cause in the future will be avoided by the adoption of the system recommended by the Federal experts. It is further chained that the method urged by the toverneam will cost the oil men liess and that there will be less that there will be less right that the method which has been in vogue.

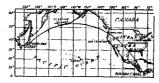

#### Mapping the Sphere on a Plane

C ERHARD KREMER or "Gerardus Mercator," as the fifteenth century mathematician and geographor preferred to be called, conterved a doubtful blessing on the earth when he invented his suffing that with the parallels of latitude intersected at right angles by parallel meridians. His map filled a certain need of his semann, but he could not have done more to confine our filess of geography. Thanks to the Mercator projection, which has found its way late the school of geography. Secanse it shows the whole world in a

The "butterfly map" of the world.

single view, one gets the notion that Canada is twice as bit as the United States, that Greenland is July as Meles, and that Alaska is much larger than Autrilla. As a matter of fact the area of Canada is less than that of the United States, and Africe is much larger than the whole of North America, while Greenland and Alaska combined would not equal half the area of Anstralia. Norway and Sweden, which on the map look like a great less rereging out of the frozen North to gooble up the small States bordering the North Sea, are actually only built the size of the State of Venezuelu in South America. Outside of Russia

The shortest course between the Panama Cangi and Yokohama passes through the Aleutian Islands.

there is not a single country in Europe half us big as Colombia

All our geographical conceptions are due to the fact that the Mercator projection makes it necessary to expand the polar regions of the earth to the full extent of the equator. Not only are our impressions of the relative sizes of land areas greatly distorted, but we are also misled as to the relative positions of various locations and the shortest course to pursue in travel-ing from one point to another. For instance, a schoolboy would tell us that the shortest course between the Panama Canal and Yokohama, Japan, would take us through Hawaii. and you could not make him believe otherwise without showing him a globe and letting him stretch a string from one point to the other, when much to his surprise, he would find that the shortest course would be to travel lanck through the canal to its Atlantic end, taking a northwesterly course that would carry him near Galveston, and up to Portland before he struck the Pacific Ocean, thence up through the Alentian Islands. The accompanying map is a Mercator projection of a part of the earth, the apparently shortest course between the Panema Canal and Yokohama by a dotted line and the really shortest course with a heavy full line. On a globe it is easy to see that the bulke of the earth makes the dotted course considerably longer than that shown to

The whole difficulty like in the second of the surface of a sphere on a plant, which it is disputed that purpose of a sphere on a plant, which it is disputed by language the decision of the sphere o

been developed. It is known as the "butterfly map" and was originated by B. J. S. Cabill, an architect, living in San Francisco Because of this contribution geography, Mr. Cahill has just been elected a fellow of the Royal Geographical Society of London. The may is similar to that of the grange lobes, except that fewer lobes are used, and instead of being connected at the equator, they are connected in the northern temperate one, so that no large body of land, with the exception of one edge of Greenland, is cut by the lines which divide the map into sections. Mr. Cahill originally made this map out of a rubber ball, a couple of inches in diameter. On this he scribed lines of latitude and longitude, 221/2 degrees apart, and drew in the map of congressed, 22% excrees spart, and drew in the map or the world. The equator was represented by a red line, the meridian 23% degrees west of Greenwich by an-other red line that was extended around the earth, and a third red line was put in at right angles to both of these great circles, which would bring it to 1021/2 degrees west of Greenwich. Where these three great circles intersected, the ball was cut with a sharp kuife along each line for a distance of 221% degrees from the point of intersection. This divided the globe into eight equal parts, four north and four south of the The cuts were then continued southward to liberate the four southern lobes, and one of the cub was continued northward so that the globe could be opened out and laid flat, as shown in the illustration No little was the distortion when the globe was flattened out, that even the paint on the surface of the ball did not crack. On releasing the map, it jumped back to its spherical form, becoming a globe again. On examining this man, it is easy to see how much shorter is the course from the Panama Canal to Yoko way of the Alcuttan Islands than by way of Hawaii. The "hutterfy" projection shows how the land radiates from the north pole in three streamers. It represents the best attempt so far to map the globe on a

#### Texas Sulphur

TEXAS is destined to play an important part in the production of sulphur for the world's consumption Beginning on November 19th, 1912, sulphur in paying quantities has been mined from the Freeport Sulphur Company's new field at Bryan Heights, near Freeport, Texas.

This latest large deposit to be worked for commercial and industrial purposes is located about three miles from the mouth of the Bracos River, the largest navigable river west of the Mississippi, and within view of the Guif of Mexico. The sulphur deposit is practically located at title water.

The sulplur at this mine is found under conditions very similar to those existing in Calcasieu Parish, Louisians, which mine was recently fully described in the SCENTIFIC AMERICA.

The area of the Texas deposit is something over 660 acres, and the sulphur content of this mine is probably somewhere in the vicinity of seventeen million

The process of mining used at the Texas field is time of introducing hot water into the formation and reserving the sulphus in a molien state by pumsquire, it to the surface. The batic system of mining by this process was patented by Herman Fresch in 1899, the patents for which expired in 1899. At the Prespect Sulphur Company's min, however, the application of the process differs in some respects from that used by Mr. Franch, and the same results are arrived at by spaceoins different methods.

"Ministrial" to conduct more man ventrouner trans-tion insulations, who has detended to design conducts. The continuer, who has detended to design conducts as the continuer, who has detended to the will be should be to be true to convey steem and water rought the same pipe; and if he wishes a metahotory of sigher divisition in a steem heating system, for mapple, he provides exparator return pipes for the outdisappe, no provision separate retains upon no two out-flowing steam and the returning water of condensa-tion. It is only beginning to appear, however, that the same laws which are recognised for even, air, water, s, hold good also for the flow of human me cules which constitute the elements of the contents of a modern crowded street.

In meatly every large city to-day there appears : tendency to enforce traffic regulations intended to per-mit the most conflicting elements to be operated to gether, and the result is naturally the impeding of the very traffic which it is desired to help.

he very general introduction of electric stre us increase in the number of autoand the transmooth increase in the number of auto-mobiles, might well be supposed to improve the means of setting about, but as these facilities are increased there appears to come with them a continual increase

in plans for reducing their efficiency. Thus, the automobile enables far higher speeds to be Thus, the automobile enables for higher speeds to be statuned, both for persons and for merchandles, than could be secured by the older means of transport. Instead of welcoming and utilizing this advantage, there immediately appears, on the contrary, such speed likeliations and traffic regulations as act to neutralize very largely the great improvement which has been developed. The ostensible reason for such obstructive thods is the safeguarding of the foot passenger; the real reason is the attempt to conduct the modern and the antiquated methods of locomotion upon the san highway, thus impesing upon the machine the limitations of the man.

tions of the man. If such a plan had been tried with the steam rail-way, all the forebodings of the conservative element of the savity misceenth century would have been realized, but foreunately the railways were enabled to use their own right of way, and the advantages of the application

of steam to transport were not lost to society.

If the real capacity of power-propelled machinery is to be gained in transport in cities, there is one funds is to be gained in reasport in cities, there is one ruine-mental condition which must be observed: the segrega-tion of foot and vehicular traffic. This is such a simple and obvious proposition, and has been so suc-cessfully applied in certain isolated cases already, that as most surprising that it has not been put into

Take the foot passengers off the surface of the treets entirely; and leave the highways solely for

tions, so that traffic regulations may be framed for but one kind of transport, thus immensely simplifying this portion of the problem. Since we may assume that, for economic and sanitary reasons, the horse will soon disappear altogether from city limits, the surface of the disappear attogetime from city mints, the entired of the streets would then be used entirely by power-propoled validies, and it becomes necessary to provide elevated sidewalks for the pedestrians. Such elevated sidewalks need not be heavy or costly, and would leave the entire middle of the street open, with possibly open the entire mindle of the street open, with possibly open-ings at points along the building line as well. The pedestrian would thus have a level, continuous walk, bridging all streets, and remaining unobstructed at all points at all times.

The feasibility of such a plan needs no argument; It requires only a visit to any one of the great bridges crossing the East River at New York, or a promonade upon a "boardwalk" at any seakide resort, to speak for

itself. In the city, however, it offers such special ad-vantages as to demand further emphasis.

The provision of a perfectly safe, smooth, and accesswalk, at the first fic or level of all buildings would add immensely to the value of store fronts, and solve many of the problems of shop and residence construction in cities. Many people would gradly walk considerable distances upon such a free and sate path, who now dread the dangers of street crossings. The considerable distances upon such a free and safe pull, who have dread the dangers of street crossings. The removal of the dangers of street crossings. The removal of as important cause of surface congection would partial as jumple greater, freedom of traffic upon the highways, that the sidicatery of automobile vehicles would, but greatly enhanced. The electric cars, given the matter of the street, would define their partial controller in the street, would define the first account the path of the speeding automobile to fine streets as the street, which is the street of the streets of t

side, providing separate conduits for different kinds, sed only application to the flow of people, to permit isir rational and satisfactory operation. An important feature in the possible installation of elevated side walks in a city such as New York, appears in the me per in which it might be constructed gradually as doner in which it might be constructed gradually, as de-manded. Thus, such sidewalks might be built on Broadway from the Battery to Union Square, there sloping down to the surface level until further extenstons were required. As each new section were added, it could be put into immediate use, thus differing from any important construction which cannot be used until wholly completed.

An important extension of the principle, and pos ably one which might be first put into operation, would be the introduction of a system of bridges connecting the upper floors of tall buildings. If, say, at the tenth floor level, the cross streets were spanned by foot bridges of ample width, enabling foot traffic to pass erution would freely along, without descending to the lower levels, there would be a marked relief to the surface congestion. Many people would remain upon the upper levels during the noon hours, taking luncheon at son venient restaurant or club upon the higher floors, and walking a portion of the distance up town at night, and the distribution of elevator service thus effected might be found most advantageous. For many pur-poses such an upper traffic level would increase the poses such an upper trume even would increase the values of the corresponding floors of the buildings, since such upper floors would become another street level for business and for the display of merchandise Aperi from the advantages already enumerated, the

segregation of foot from vehicular traffic upon differvels should lead to further developments been felt by many that the continued construction of tall buildings, both for intenses and for residence, would inevitably result in darkened streets, congested living quarters, and other disadvantages. If, however, the necessity for descending were removed, and the net in the necessity for descending were removed, and the lenst until the more congosted quarters were passed, many of the objections to tall buildings would disappear. The lower floors would follow the tendency aire ady begin ning to appear, and be used for storage, for the hand-ling of heavy merchandise, and similar purposes, freed sadvantages of obstructing foot traffic, whi the facility afforded for free and safe movement ut higher levels for business, shopping, eating, and rest dence, would restore the pedestrian to the brighter purer air, and safer movement formerly enjoyed n the surface

It is possible that, upon some intermediate level, the wing road" in the form of the traveling platform, might follow the general unlift; while more remotely, but yet not beyond practical vision, may appear the coming of serial transport.

One thing must be firmly understood, however, that the principle of absolute segregation of foot travel from kind of vehicles is essential for relief, and thus any plan which proposes to place both automobiles and pedestrians upon the same level, would be fatal to suc-cess. The power vehicles should be kept absolutely to the surface, and there given unrestricted facilities for ed, weight, and numbers; and the fest levels multitained for absolute freedom for pedestrians, with the possible exception of carriages for small children

The resulty of the problem which is already awalting The resulty of the problem which is already awalting solution, will be appreciated when it is understood that u single modern structure, such as the Woolworth Building, New York, contains 10,000 people, the popu-lation of a good-sized town, and that all these people must enter and leave at leave once a day, and many of them more frequently. Such problems of congestion are not to be met by the conciment and enforcement es and regulations restricting and impeding the automobiles or street cars, the very means by which, if unrestricted, much of the traffic might be relieved

Rather, the opportunity for full speed and freedom of movement should be given; as it can be b) taking the foot passenger wholly out of the way, and giving to him also that greater freedom and entire safety to which he is cutitled.

#### The Current Supplement

MUCH evidence points to a point 273 deg Cent. below the freezing point of water as the absolute zero of temperature. Cold approaching this presumably prevalls in interstellar space, and has also been produced in the laboratory. Reflections upon these facts dured in the monotory. Acceptance upon increasing from the subject of an article in this week's beauc of the SCENTURO AMESICAN SUPPLEMENT.—Dr. A. Gleichen writes on "The Human Eye and the Photographic Camera—Points of Similarity and of Difference." An account of the measurement of the luminosity of the glow-worm is given by H. D. Ives and C. W. Jordan, showing that this creature is fifty times more efficient showing that this creature is mry times more enterent than our best light sources.—A laboratory for research in optics and photography, just completed by one of our large manufacturing frame, in described, and the scope of its work outlined.—Food. Haber describes his process for the graphestic production of ammonia.

#### A Suggestion for Flood Prevention

To the Editor of the Scientific American: Like Mr. F. A. Day of Ohio, I have followed with interest the various articles on flood prevention, and have often wondered why no one mentioned the plan which he suggests in your issue of June 28th. It seems to me by far the most practical plan so far suggested

I am not acquainted with the middle West t extent, but in most places the streams flow through numerous flat meadows admirably adapted to such a scheme, with benefit both to the meadow land and to the country below

Could not Mr Day's plan be improved upon, how count not still the same entirely across the foot of the meadow and providing a suitable culvert in the stream bed of such size as to carry a little more than scream new of semi-mass as to carry a fittle inforestinate the normal flow of water. Then if the stream rose above a certain height the additional flow would spread over the needow until the water had risen to the spillway which would be provided in the top of the dam. In the same way the receding water would flow out gradually till the basin was empty. By providing larger culverts at certain points part only in tunes of extraordinary flows. In this way the entire action could be made automatic, no attendance being required for closing flood gates, etc.
Somthbridge, Mass. H. F. Ammidown.

#### Solar Physics Observatory for New Zealand

To the Editor of the Scientific American It may interest you to know that owing to the generosity of Mr. Thomas Cawthron of Nelson, New caland, a solar physics observatory is to be ere Zealand, a solar physics observatory is to be erected in this part of the world. He has promised to build, equip and cudow a solar physics observatory, at a cost of about ten to twelve thousand pounds. The site will probably be on a summit known as "The Pringe," at an elevation of 2,500 feet above sea-level, and easily accessible. The annual average of direct sundino is 2,500 hours, and the rain register annual average during the past thirty, years is 37,88 faches. Nelson has been termed the climate paradise of New Zealand, and according to Prof. Archibald, the well-known meteorologiest. Nelson is very mitchle for the known meteorologist, Nelson is very suitable for the establishment of a solar observatory.

MARY PROCTOR 159 Collugwood St., Nelson, New Zealand.

#### A Few Words of Appreciation

To the Editor of the SCIENTIFIC AMERICAN

To the follow of the Schritzic American.

I cannot resust the temptation of influeting another letter to let you know how I appreciate some things you have recently published. Some issues back you published a redpe for "Salt-rising Light Bread" that has been worth the subscription price of the Schritzic American for many years to us. In your usane of May 31st you have an article entitled "The Embradery of Knowledge" which I thus! "The Embradery of Knowledge," which I think very appropriate and useful. There is a sontiment gaming ground that the hey should be taught first how to make a dollar and then how to keep it. Now if we become only a nation of money seekers, what will we be but a race of human hogs? All esthetic sentiment and refinement will soon be gone. When wealth is the only object of ambition, any method of obtaining it is countenanced, and so there arise many evil practices among the people. there arise many evil practices among the people.

I have the first astronomy I studied at school with
a frontspiece map giving the sublime home of
the mythological gods. I next got interested in
this matter in the Æneid of Virgil; bave since followed it up in Dante, Shakespeare, Homer, and others, as well as the more prosaic works of Anthon, William Smith, Lempricee, etc. Much pleasure has it given me. The man who wrote that article has my heartfelt thanks and host wishes in all respects. Woodbury, Tenn. W. R. SMITH.

#### The Scientific Employment of Men

#### Standardizing Human Character

By Herbert Newton

PICK up any dally newspaper published in any large American city and you may read dozens of advertisements worded thus.

WANTED-Batry clerk in receiving department of wholesain drygoods house Not over forty. Must be conscientions, accurate, and experienced. Ad-dress X Y Z., Boz 241. The Planet, Uptown Office.

A hundred applicants write. Those whose letters are least ungrammatical are invited to "call and see our Mr. Jackson between nine and ten o'clock to-more worning." They duly appear. Mr. Jackson looks his men over. The old ones, the shabby ones, the shabby ones, are promptly dismissed. Mr. Jackson may be right or worning in disposing of them thus summarily. The rest he questions. Invariably he asks: "What is your experience?" Finally he elected a man not unattractive in apporance, one who has been in the drygoods

selects a man not unattractive in appearance, one was now seen in the separation business for five years.

Will the man stay in his new pince? Will be be acceptable to his fellow workers? Can be be counted upon in an emergency? Will be have the interests of the house at heart? Only time can tell; not Mr. Jackson.

This is the time-honored "hiring and firing" method-wasteful and expensive. But is there anything better? Is there any way of standardizing men as machines and materials are standardized? Is there my way of specifying human characteristics as accurately as belting and steel are specified for a chine shop?

Business men have thus far interested themseives but little in this matter. Theirs are still the hit and miss methods of antiquity. They try aman for a time, which is equivalent to sampling a patent medicine or demonstrating a machine, and they cherish the illusion that thay are proceeding in a practicel. business-like way.

The alive manager of one large firm once tried three bundred candidates before he succeeded in obtaining an even passably efficient force of twenty-five asis-num. The cost of engangine, partially training, and finally seeding out the 275 unit summand to over \$80,000. This was the actual money lost. The waste of time, energy and enjoyertunity for profitable asise can be scarcely waste; of time, energy and enjoyertunity for profitable asise can be scarcely

Business men forget that the demonstration method is expensive and that Dualness men longer that the demonstration method is expensive and that it may sometimes prove disastrous. Sometimes they try to cast upon another the cost of demonstrating a man's fitness. Hence, it is a common practice to appropriate men who have demonstrated their ability in some enterpriss. Where would the American many be if it attempted to officer its ships by appropriating

would the American navy be it it attempted to onneer its suips by appropriating British, French, and Japanese officers of alkillity?
Selection on a basis of experience (Mr. Jackson's method) is common, but yould pusselization for the prediction of the properties o without aptitude is worth little; and that aptitude without experience may be worth much. Experience is important, but it is easily acquired when there is aptitude, days or weeks giving a profelency not otherwise accumulated in mouths or years. But how can aptitudes be judged? Psychological tests have been advocated, but their application is exceedingly limited. A man is not necessarily a good locomotive engineer because he can distinguish red from gre-because he responds quickly to signals. No psychological instrument ti devised can determine whether he is careful, whether he has press

ideally, an efficient commercial or industrial organization is correctly designed Ideally, an efficient commercial or industrial organization is correctly designed as to functions and their inter-relation. Each individual in the organization, whether executive or subordinate, is fitted by natural aptitudes, training and experience for his function, and all are associated with reference to their common adaptability and harmonious co-operation. Engineers, executives and organizers have worked on the problem of design until it now approaches the ideal. The clarat or organization with line and staff functions devised by Ma. Harrington Emerson and the functional foremanship plan of Mr. Frederick W.

Taylor are eximples. It remained for someone to bring the problem of scientific selection and assignment of employees out of chaos and hapshaard methods into scientific efficiency. This has been and is being done practically in several large commercial organizations, according to a pian originated and made the basis of supplement departments by Dr. Katherine M. H. Blackford.

Dr. Blackford proceeds on the principle that "the largest wass of money, the finest materials, the latest and best equipment, the most cleverty and intelligence."

out beforease to their finess. It is also deplorably wasteful of time ann money of the employer and of time, energy and psycholal imprintion of the employee. Mr. Harrisgion Emerson has estimated that "the yearly money lost in direct cost on the average mechinist of our 170 her cent efficiency (not by any means as manusal standing) is nearly \$5,000; not counting the lose of profit on output. This loss in efficiency increases as the position becomes one of greater importance." It is but one step in advance to use the cut and try or "thre and fire" method of selection by requiring actual demonstration of fitness ou the part of

r. Bisckford has for thirteen years carefully studied men and won their work, in their amusements, in their mental and physical allments and abnormalities, in their religion, in their social and commercial relationships and in their crimes. She has studied them in all vocations, in all parts of the Usided States and Canada, and, during a four of the world, in eighteen foreign countries. In her files she has details and complete records of her examinations of 15,000 persons, and summarized and classified records of her observations.

As the result of her studies she has devised a scientific method of judging char-As the result of her studies she has devised a scientific method of judging char-ceter, a method which judging caccurate, clear, and easily applicable information as to the requirement—in human aptitudes, trating and experience—of each function in the organization; which provides for the selection of human mate-rial by methods for determining its inhorent and acquired qualities; which can at to intelligent examiners and used in analysis rapidly, unobtrusive it requiring more than passive co-operation on the part of the appliand evitable twelfaring more than passive co-operation on the part or increasing court; and leastly which provides the management of any organization accurate information as a basis for associating workers and executives in such a way as to realise the greatest possible efficiency. True such

The system which she has devised deals entirely with externals. In an intui-

tive way we all recognise the value of external characteristics in judging human capabilities. Even our language indicates it The "roving blue eye" is not an empty phrase. The words "thick skinned" and "thin skinned" council both empty parase. The worse times assigned used that samme common both physical and psychical degrees of sensitivity. The sensitive, delicate minded man usually has a fine textured akin; the coarse-minded man a coarse textured skin. It is an embryological fact that the skin was and is the original sent of all sensations, and that spinal cords and nerves are but modified and specialized inturned skin. Of necessity a man's skin indicates the texture of his brain.

Dr. Biackford holds: "It is a law of human nature having universal application that the size, color, proportion, form, texture, consistency and structure of an object indicate its function and use."

As the result of all her investigations and studies she has determined mon As the result of all ner investigations and studies such as devertinated upon time fundamental physical properties, variations and combinations of which indicate the characteristics not only of fundam beings, but of all other material objects, whether animate or inanimate. These nine fundamental properties are leasure, size, color, form, structure, consistency, proportion, expression and experi-

Each of these nine properties has a distinct manifestation in every perso For example, texture may be fine, medium or coarse. Size may be large or small and all degrees between. Form may be extremely convex in general tendency or extremely concave, with all extremes of convexity and concavity, and with binations of convex and concave features of face and body.

Structure may be slight and delicate, square, bony, and muscular, round and Structure may be slight and delicets, square, bony, and nuncular, round and corpulent, or any degree and combination of these. Consistency may be very bard, very soft, elastic or varying gradation of these. In proportion we find simuse every possible combination of proportions of different parts of the body, head, and face to one another. Expression has almost as many variations as there are people, as does also experience.

Dr. Blackford's Inventigations indicate that each of the nine elements shown

rates is indicative of certain inborn or acquired characteristics of the

For example, she points out, texture is a great classifier of humanity. The individual of fine bair, has textured skin, delicately clisted features, steader, graceful body and limbs, as a general rule, is refined, loves beaut, and grace. and likes work either purely menial in its nature, or offering an opportunity to handle fine, delicate materials and tools. On the other hand, the man with coarse hair, coarse extured skin, and large, arguely formed feature, belies as a general rule to occupations in which strength, vigor, virility, and ability to live and work in the midst of harsh, rough, and unbeautiful conditions are prime

Mark well in this statement, however, the qualifying phrase, "as a general rule." Other elements beeddes texture may modify the final result. Also note well that these are merely suggestive examples of all of the many things that

went that there are merety suggestive examples of all of the many children that texture may indicate in the individual.

Some similarly suggestive indications of the other properties may also be given. In size, men of small stature and light weight are obviously adapted to light work, and work requiring quickness and agility, while men of large stature and heavy weight are adapted to lifting and moving about large and heavy masses of restardal when encoused in theirbeat work.

of material when engaged in physical work.

It is no secret to observant employees of labor that blondes, as a general rule, are changeable, variety lowing, optimistic, and speculative, while brunettee are consistent, riesdy, dependable, serious, and conservative.

Form is evidenced in the shape of the freatures, and of the entire body. It requires no scientist to observe that the greybound is quicker, more responsive, and less enduring than the building. And it turns out, as one might naturally expact, that the man who resembles the greybound in form is quicker, keener, made responsive, and less enduring that the building in derivative of the second s

## Colonel Goethals' Private Car

of The Yellow Devile's the pet workers have the pixel workers have the rivide motor car of Colonel Goethals. It is apparently a combination of automobile and "dulky," as it has a powerful gas engine with hood like an automobile and a cowacther like a locumotive. It runs on the tracks of the Pannama Rathroad and will take the chief engineer to any part of the rounder of the desired of the pannama Rathroad and will take the chief engineer to any part of the rounder of the desired of the rounder of the seen a powerful searchight, while a similar one is mounted at the reart. This sends its rays to any point that may need special topsection during a night trip.

## Aerial Divers

THE highest point on the face of the earth rises 28,002 feet above the sea This peak of Mont Everest pokes its nose above the life-sustaining stratum of the earth's atmosphere. To reach such an earth's atmosphere. To reach such an elevation, it is quite as necessary to employ oxygen supplying apparatus us it is for the diver who descends into the sea. The highest point ever reached by man without the aid of special breathing apparatus was 8,600 meters or about 28,200 feet. This was on April 18, 1878 when the balloon "Zénith" left La Villette with three passengers aboard and came down e hours later with two of the pas-ters, MM. Sidel and Croce Spinelli, suffocated and Gaston Tissandler all but That record for height has just been broken by a wide margin by the balloon "Icare," which, on May 28th of this year, left Lamotte-Breull, rose to an altitude of over ten thousand meters, or nearly thirty-three thousand feet, coming to the ground five hours later. engers, MM. Hiensimé and Jacqu the passengers, MM. Hemains and Jacques Schneider, were photographed by the third passenger. Albert Hemouque, at the 10,000 meter elevation. The photograph is re-produced herewith, and it shows the seromatus well bundled against the extremely cold weather at that altitude and each fitted with an oxygen-breathing apperatus. Each apparatus consisted of a container for 1,600 liters of compre oxygen, a nose and month attachment con-nected to the container and a means for regulating the feed of oxygen as needed.

## Railway Automobile Newspaper

DURING the Gildden tour from Muniapolis. Minis. to Gincler National
Park, Montana, July 11th to July 10th, a
daily automobile newapurev was printed
on the hotel train of the Great Northern
Italiway, which accompanied the automobile tour to furnish cetting and sleepling accommedations for the motorists.
The newappare plant was installed in a
dynamo baggage cur. The plant included
a libutype machine, a cylinder pross, and
au cugraving outfit. The staff photographer's daily story of the tour was told
with halftones prepared in the engraving
plant. The accompanying photograph
shows the "composing room." To run the
plant a four horse-power moor was used
which obtained its power from the car
dynamo

## A Noise Orchestra

In order to add a touch of realism to moving picture exhibitions, it is enabour ary to punctuate the pictures with the noises one would hear if he saw the same scenes in real life. Herstofore this has been done only occasionally and half-heartedly for the reason that many of the sounds called for were difficult to initiate without special appuratus. However, a machine was demonstrated at the recent moving picture exhibition at Grand Central Palace, whereby any number of different lifelite initiations can be produced by merely straining the proper crusic or pressing the proper pedal. This stagenoise cabinet is the invention of Mr. Samuel Lapin. More than a handred various sounds can be produced. Not only are all sorts of domestic and wild animal calls produced, but also sounds. For instaget, there are fifteen are

different lands of whether the comment was from the whether the control of the co

## Egyption Minerals

A SIDE from its agriculture, attention is being directed to the mineral rich of Egypt, it being naturally asked wheth neath the immence desert tracts extending beyond the Nile valley. A leading French authority Prof. Potier treating in this subject refers to the recent discover of oil fields at German on the coast no the mouth of the Suez Gulf. One so ing operation traversed a 6-inch layer of osokerite at a depth of 250 feet, and within the last few months the petroleum question is quite active. We may men-tion the first boat load of 6,000 tons of di starting from the Red Sea, and new petroleum fields have been lately discov-ered, it is stated, toward the Sinai region. ered, it is stated, toward the Sinai regome-Turning to copper production, Egypt wis-rich in this metal in ancient times, but the mines were of such kind as in the the mines were of such kind as security worked and for this reason now exhausted. Traces of the copper mines have been found, in which the ore took the form of silicate and carbonsti However, a good vein of silic found on the east cost of Sinai peninsus and other deposits are seen in neighboring places. Manganese deposits are observed in this region, and good lead zinc beds as well. Gold is already below taken out at several centers in the ex-treme south of Egypt, and to the south of Assonan there have been lately taken up the ancient gold mines of th of the Ptolemies. On the shore of the Bed Sea at Sukari quartz having three ourses per ton is now worked. Precious stone are represented by emerald, turquoise and peridot. Phosphates seem to be a mere immediate and sure source of wealth for this country, and several beds in the Nife Immendation this country, and several begs in two valley show 70 per cent of phosphases. The richest points, however, seem to be at Rachid in the Takish cesis and at signed out in the Libyan desert, 300 miles from the Nile vailey, but the future extension of the railroad will bring the within reach

## **Dutch Dairy Methods**

THE most minute precautious are used in the model dairy farms man also large centure, in Molland in order to greature miticabeling the greatest degree of the month of the greatest degree of the minute of flood given to the cows and its question of flood given to the cows and its question are food given to the cows and its question roughly or looked after so as to avoid digastive troubles which are known to affect the quality of the milk. ## Befrigerating Machines for the Home

DURING the hot summer mouths the comfort and happiness of residents in suburban and country places are largely dependent upon the visits of the iceman and the inventor who is able to produ a small refrigerating machine which will emancipate these people from their ab-ject dependence is sure of his reward. In o prove a success, such a machin should be us durable and as easily oper ated as the ordinary home steam heating apparatus. Unless the machine can be ly and efficiently operated by the aver-broughold servants it will be impracticable, for the expense of skilled labor would render the use of such a machine prohibitive. Many attempts have been made to produce such a machine, but with varying success, for there are many diffidevice

For this purpose the compression ma-chine probably affords the greatest prom-In this machine there is a cor sor which acts as a pump, drawing in the vapor of the volatile refrigerant on one stroke and compressing it and forcing it into a condenser on the return stroke. take away the heat of the gas due to the on and also the latent heat giver out by the gas when it is converted into a The liquid refrigerant being under high pressure is forced through the exon valve into the refrigerating col or chamber where it evaporates and cools the air or brine in contact with the outer walls of such coil or chamber. As fast as the vapor is given off by the evaporatser and again forced into the condenser where it is liquefied. The volatile refrig-erants generally used in compression maare anhydrous ammonia, carbon dioxide or sulphur dioxide, ammonia hav ing the preference. Where ammonia is used the pressure in the condenser must be maintained at about 175 pounds in er that it may liquely when cooled or of ordinary temperature. With pressure the packings of the com-or must be very tight and on a small like the friction losses are very high-ing the condenser water fail for any length of time, the pressure would rise to a point where some of the pipe connec-tions would be liable to burst and fill the , would be liable to have and fill the so with early furnes of strong an-ing the cogning into very queerl use of the cogning into very queerl use to make an or cooling the large re-resident completed. They give very ma-they make they have been and they make they have been and they make they have been and the

desired. No skilled attendant is required unless in case of emergency.

Fig. 1 shows a small ammoda machine located on the top of the ordinary refrig-erator with the cooling coil located in a tank within the refrigerator. Within the refrigerating chamber is a thermostat which, at a certain low temthermostat which, at a certain low tem-perature, closes and at fixed high tem-perature opens a valve in the cooling water supply pipe. The pressure of this water, by means of a disphragin device, s a switch in the circuit to the elec tric motor which runs the compre Should the water supply be cut off by the thermostatic apparatus or fail for any cause, the lack of pressure under the dia-phragm will open the switch and stop the motor. In this way the machine operates only when there is an adequate supply of cooling water. Of course, much depends paratus, but there appears to be no in-herent difficulty in constructing such devices so that they will perform their func tion properly if given a little intelligent care and attention

At first glance it would appe phur dioxide was peculiarly adapted for on account of the fact that it fiquefies at very much lower pressure than either mmonia or carbon dioxide; still it has one serious defect when used in the conventional form of compression maci The suction pressure must be below that osphere in order that the liquid in the refrigerating coils may evaporate at a sufficiently low temperature to effect refrigeration. With such low pressure als will inevitably leak in, especially through the peckings of the compressor, and in time will render the machine inoperative se the air will not liquely, and th fore its circulation through the mach ot effect any refrigeration. There is canı also danger of brine leaking into the system, and when this happens the machin is apt to be seriously damaged, as th water combines with the gas to form sol-phurous acid, which is very corrosive. However, two Frenchmen have brought out a sulphur-dioxide machine, shown in Fig. 2, in which these difficulties have have never mental and the sulphur-dioxide machine, shown in Fig. 2, in which these dimoutize nave been overcome in a very ingentious way. In this machine all moving parts are con-pletely inclosed in hermetically sealed, des-ings, thus preventing any locationity of air leaking into the aystem. In external ap-penrance this machine resembles a dumb-

condenser, will rotate in cooling water, chinc illustrated, the condenser is in the The two compressor cylinders are made form of an apright tank containing a float. in one heavy piece which is loosely hung on the hollow shaft and the pistons are reciprocated during rotation of the cusing by means of eccentrics fixed on the shuft Ring valves are used to control the suction and discharge.

In operation, the compr the vapor given off by the liquid sulphur dioxide evaporating in the shell B, compress it and discharge it into the shell A where it is cooled and liquefied and again flows back to the shell B to be evaporated. In case the supply of couling water faile from any cause, the pressure rises, but before it can become dangerous the pres-sure overcomes the weight of the compressor cylinders and they rotate with the shell. This means for avoiding high pressure is a very important feature of the machine, for it is infallible in operation and independent of human control. The brine tank may be inclosed in the refriger ator or the cold brine may be pumped through pipes located therein. In case ice is desired it can be obtained by filling small cans with water and placing then cold brine

By actual test it has been shown that these machines are quite efficient and can be run continuously for many years without repairs. As all the moving parts are inclosed the machine is practically "fool proof" and any one with sufficient intelligence to turn on an electric switch and the cooling water can operate it. In case ficient pressure the machine may be operated by a hydraulic motor and the wast water from the motor may be used to coo the condenser. A careful study of this chine will show that it has many excellent features that should make it a and it is believed that the prediction is warranted that when home ic nachines come into general use, they will be of this type. The original putent on this machine has expired and an attractive field is now open to inventors.

Attempts have been made recently to adapt the absorption in use and such a machine is shown in Fig 3 In this type of machine a conden refrigerating coil are used just as in the ssion machine, but in lieu of a compressor a large boller known as the generator-absorber is used. This boller is partially filled with strong aqua am-monia and heat is applied to drive off the leaking into the system. In external 20 month and heat is applied to drive off the and a pair of steel rods, which connec parance this medicine resembles a dumbi-immonda in analytons condition into the ball, with an extension on one cut for a condenser where it liquefles. When prache pairs, This structure rodsic is it ideally all of the ammonia has been exhausting in two separate tanks, is dust pelled, the liqued in the holter is permitted just the extension and the interest of the content of the cut the pendulum lengthens by the covered shell 2, which serves as the to cool dewns, and it then readily absorbed cooling, will be particulty immored in brins; the ammonia waper as fast as it is given before needing rousewal of any parts.

temperature can be maintained as low as while the larger shell A, which acts as the off in the refrigerating colls—in the ma-At the end of the heating period this condenser will be nearly full of liquid ammonly and the float in rising will operate n system of levers to cut off the gas burner under the generator and divert the flow of cooling water from the conden to the generator-absorber. At the end of the absorption period the float in descend-ing will again reverse the valves. The success of this machine also depends upon the automatic apparatus properly performing its function.

## This Push Button "Talks Back"

I T is reported that a patent has been taken out in Norway and applications filed in England and Germany for an electric push button which when pushed has connected with it devices by which the person whose attention it is desired to attract may respond so that the one signaling knows he has been heard and the one being called is saved the annoy-ance of latening to repeated ringings. The result is accomplished by an electric magnet provided with a buzzer and the convenience of the unprevement appeals especially to those who may be summoned during the night, such as physicians and nurses, and should be found useful in conmeetion with call buttons called cannot always monediately respond.

## A Novel Electrical Clock

Daniel, Hrawbaugh, a plonter ceptible inventor, whose activities especially in tolephone lines are well known, in the late sixtles built a clock which is now running at Carlisle, Pa . In the office of his son, Charles H Drawbaugh. The clock has continued to ate since 1870, except when being moved from place to place, and operates without winding. The pendulum, weighing fortyfive pounds, is operated by an ordinary electro-magnet and a permanent magnet armniare, the current in the electro magnet being reversed as it passes the armsture. The buttery consists of a plate of copper and another plate of Iron, which are buried in the earth These plates give a small electro-motive force, and enough current to keep the pendulum swinging A peculiar feature of the clock is the compensated pendulum, which, instead of being in the conventional "gridiron" form, comprises a pair of brass rods and a pair of steel rods, which connect with each other and with the pendulum bob by means of two short levers, so that the bob of the pendulum will be lifted to just the extent the pendulum lengthens by

## Notes for Inventors

A Sliding Racing Shell Seat .-- Adries Gerardin and Charles Sauve of Pembine N. D., have secured a patent, No. 1,058, 855, for a sliding seat for a racing shell with a spring which draws the seat normally toward the bow of the boat, the seat con-tacting with an anvil at the completion of its forward movement.

Phonograph With Disk and Cylinderrhonograph with Disk and Cynneer-record Mechanism.—In patent to Adolph Schwer of Buffalo, N Y., No. 1,058,911, is shown an apparatus in which are com-bined a phonograph disk-record mechanism and a cylinder-record mechanism together with a driving mechanism which may be clutched to either the disk or the evlinder record mechanism as desired

A Coffee Substitute. -John L Keilogg of Battle Creek, Mich , has patented, No. 1,059,471, a coffee substitute in which there is an admixture of a starchy material and syrup which has been beated and coninto and expanded into a puffed, porous mass browned and pulverized, the starch being dextrinized and the syrup being in the form of caramelized sugar

An Electric Washing Machine .- In patont No. 1.059.071, for an electric washing machino, issued to Richard D Robinson of New York city, are included electrones fed from a source of current supply and means for reversing the polarity of the electrodes. In the use of the invention chlorin is utilized as a bleaching element and the chlorin is produced by the dreet action of the current passing between the electrodes

An Inventor Congressman .-- The Official Congressional Directory for the first see of the 63rd Congress, issued April, 1913, contains short biographical notice of the different members of the House and Senate. That of William Henry Wilder, representing the third district of Massaetts, rocites that he was a merchant until 29, manufacturer and inventor, and has had assued to him over 50 patents, also that Mr Wilder is a lawyer and expert in patent matters. He was elected to the 62nd Congress by 130 and the 63rd Congress by 3.203 plurality

Five Can-filling Patents .- Walter J. Phelps of Baltimore, Md, assignor of one half to Frank Gebbie of Rochester, N Y, has seened five patents for can-filling machines or apparatus in which the machines e cans through a small perforation of such a size as to prevent spontaneous ontsuch a size as to prevent spontaneous out-flow of liquid therethrough, the small filling opening being also casily closed by a single small drop of solder, the smaller the open-ing the smaller the drop and less the hability of any of the solder entering the can as a loose globule. The patents include other features and are numbered from 1,058,093 to 1.058.007 inclusive

A Folding Pistol. -- Patent No. 1,059,405 has issued to the Sumplex Arms Manufacturing Company, Denver, Colo., as assignee of Horace M. Sprague, also of Denver, for a pistol in which the barrel is hinged to the handle and is adapted to fold against the handle and the spring-actuated harm-mer in the handle is cocked by the folding barrel, a dog being provided for locking the hammer and a two-part trigger bong carried by the barrel with the lower member of the trigger engaging and tripping the dog to release the bainmer whe

edway, New York city, undertook the Broadway, New York city, ungardox take sweeping of the avenue. At that time the condition of Pennsylvania Avenue, the national parade ground, was such that Mr. Critchenson had to put about one hundred laborers to work eleaning off the nearly foot deep mud before the operation of the

A Collier With Two Hulls,formed with two spaced apart side portions so arranged as to receive between them the ship to be coaled and having a bow portion connecting the side portions and delivery pipes for directing the coal from the side paper for directing the coar roun the side portions into the ship between them, is shown in a patent, No. 1,059,201, to Charles Pacquier of New York city.

Two Nikola Teala Patents.—Teala has secured two patents, No. 1,031,142, for a rotary pump, and the other, No. 1,061,206, for a turbine, both of which include suitfor a turbine, both of which include sulf-able easings with inlet and outlet ports and a plurality of plane surfaces spaced apart. The inventions have already been de-scribed at length in the columns of the SCIENTIFIC AMERICAN.

Show Window and Show Case Improvenent.-Patent No. 1,060,787 to Tron O. Peterson, of New York city, assignor to Store Improvement Company, Inc., of New York, is for an apparatus such as a New York, is for an apparatus such as a store window or show case for exhibiting merchandise which has a transparent par-tition and an opaque partition in front of the transparent partition and extending

both of the transformers and a phase-ad-justing device connected to the autenna-toground circuits

## INQUIRY COLUMN

The Scientific Employment of Mer (Continued from page 62.)
a. An examination of the portraite

of a hundred great generals, pi engineers, explorers, bile racers, aeronauts, and other who lead a life of great activity will she

a general tendency toward structure on the lines of the square—square face, square body, square hands. Reference to the portraits of great judges, financiers, organizers, and com-mercial kings will show a general tendency toward structure upon the lines of the circle—round face, rounded body, and a tendency to roundness in hands and

Anything which is hard in consistency has comparatively great resistance and persistence. That which is clastic in conpersistence. List which is come to have statency is adaptable and seems to have spring, life, and energy within it. That rhich is soft in consistency is pliable an impressionable. These principles have en found to apply to human bein

Relative development or proportion of he different parts of the he organs of the body to one another is, in the eye of a physician, the anatomist, and the expert analyst of human character, as indication as to the relative degrees of the three qualities of energy, vitality, and -and of many other charac

encies show themselves in the expression of the face, quality of voice, gestur walk, clothing, etc. Since the human body is plastic, any emotion, thought, or tend-ency which has become habitual leaves its permanent mark in all the forms of

"Normally," says Mantegazza, "ev thought and emotion takes form in action A transitory emotion has a fugitive ex-pression which leaves no trace, but when it is repeated several times it leaves on the face and other parts of the body an expression which may reveal to us a page of the man's history"

In a similar way, a man's experiences ave their marks upon him.

The foregoing is a summary, greatly abridged, of the indications of each of the nine elements upon which Dr. Blackford and those using her plan base their judgment of qualities and characteristics Far more important however, than any

one of the nine elements is their co tion in the individual. Every individual has his equipment of all nine, and his personality cannot be understood if the significance of even one of the nine is

The importance of this consideration may be made clear by chemical analogy A student of chemistry may learn all th characteristics of oxygen, carbon, and hydrogen, but he may know nothing of the attributes of their many compounds until he has learned the significance of their combination in different proportion

Just as all human beings are combina tions of the nine elements mentionall carbohydrates are combinati

oxygen, hydrogen, and carbon.

Just as carbon, oxygen, and hydroge in one compound give us flery, caustic, and poisonous carbolic acid, and, in different proportions, sweet, healing honey, so the nine elements, combined in certain propor tions, may make of one man a degenerate thief and murderer, and of another patriotic and philanthropic citizen.

The analogy may be carried ever further. Oxygen is a gas lighter than air, colorless, slightly acid in odor and tasts. Hydrogen is also a gas very much lighter than air, colorless, odorless, and ss. Carbon is a solid, and usually hard, dense, and black.

hard, cense, and black.

None of the characteristics of any these three elements are to be found butter, moissess, phenacetin, or peppinint. Tet these three, and these th mini. Let these three and these three only, are in the substition named. In a similar way, combinations of the alone elements of human character in different proportions yield characteristics not hadicated by any one of the nine.

## The Motor-driven Commercial Vehicle

This department is devoted to the interests of present and pro

From the Chauffeur's Point of View BELIEVING that not enough attention is being poid to the human elemen in estimating the relative efficiency of the torse and the commercial motor vehicle horse and the commercial motor vehicle, are representative of the Scientific American recently interviewed a number of drivers of a birge department store in New York to get the chauffeur's side of the subject. The following questions were asked one of the drivers of an electric deilvery wagon

- delivery wagon
  Q 11d you ever drive a borse?
  A. Yes, I drave a borse for 7 years before they put me on this truck when the
  store opened—it was about 3 years ago.
- Q. How do you like the motor truck as compared with the horse?

  A. Well, I like it a lot better
- Do the other men like the motor truck as well as the horse

- Truck as well as the norse?

  A. Yes, they all like it.
  Q. Wetl, why do you like it?

  A. When I go up a street, I can get off at my old place and do not have to bother about hitching. I know that if want to stop a minute my wagon 's just as safe as it would be in the stable; there

ls no danger of its running away.

Q. Do you find you can cover more

A. I cover about 40 miles in my ront every day. I go up around through Har lem and I cover just about the same as I used to with a couple of horses (sic!), but they could only go out about 5 day

Don't von find you can cover your ronte quieker

A. No, I don't believe I cover it much quicker. (We are inclined to doubt the accuracy of this answer, particularly in

of the reply to the next question.)

When you get through at night, can't you get to the stable quicker with your truck?

Oh, yes, 1 had to let the horses take their time. I might be several miles away from the stable and then I would to let them rest a little and not kill them, but I can just turn the julce into the old truck and get through in 25 mln-utes or so lustend of more than an hour

How much power do you use on the truck?

A. I figure we use about 5 amperes a mile. There is a "guy" that reads the meter when we go in, and he says the average is about 5 a mile.

Do some drivers get more milenge on the same amount of current

Yes, and there ought to be some prizes for that We can waste the juice then we can save it a lot by constlug tf we want to.

The answer to the last question is unite significant. There is no doubt that the driver can save current If it would pay him to do so. Motormen on many street car lines are awarded premiums for economical use of electricity. How much more important, then, it is to adopt such a system on a motor car which draws its supply not from an addinated store at the central station, but from battery cells of limited capacity.

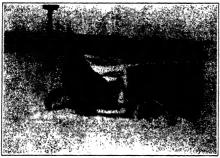

There is no doubt that a driver who is promoted to the position of chauffeur feels the importance of his advancement and does better work. Instead of a merstableman he now becomes an "engineer in fact, we should be inclined to think that it would be advisable where possible to make chauffeurs out of former team sters rather than to hire chauffeurs who had never handled teams; this, of course provided the teams or shows any apti-tude for operating the motor truck. It tos been found that the ex-test

more accustomed to loading and unload-ing the truck, and willing to do his share, whereas the chauffeur may feel that such

## The Motorcycle Truck for Light Deliveries

gasuline. Of course, frequent stops would it is entirely it materially reduce this showing. Thirty-two miles per gallon has been given as a timate, or including the oil sumption, about 60 cents per day of ten bours, covering seventy-five mile This would be about \$16 per month for Deliveries

Rasoline and oil, which is less than the gasoline and oil, which is less than the to make much impression on certain month, while, furthermore, a horse could

Motorcycle truck plowing through snow with a 600-pound load

lines of busine ss, for the reason that the deliveries are light, distances traveled are enough to justify the initial outlay for a motor delivery vehicle. But there is an other competitor of the horse, designed to meet just such a situation. It is the light weight motorcycle truck. The ac-companying photograph shows such a truck manufactured by a motorcycle maker, successfully combating a six-inci maker, successary comparing a six-nen snowfall at a speed of 25 miles per hour. The vehicle is three-wheeled, driving through the single rear wheel This makes it unnecessary to use a differential. reduces weight and does away with cer-tain mechanical weaknesses. The vehicle lilustrated is designed to carry 600 pounds in addition to the driver. The machine to started without raising the rear wheel from the ground, as is usually neces in the standard type of motorcycle. engine does not have to be cranked, but is started by the simple operation of step-ping on a pedal. This enables the driver to stop the engine whenever he leaves the truck to make a delivery, thus saving gasoline, and also conforming to the law in certain localities, without at the same time being put to the inconvenien cranking up his engine. The advantage of a motorcycle for light deliveries lies not only lu the economy of first cost, but

not begin to cover a delivery route of seventy-five miles per day every day of

## Mechanical Loader for Motor Trucks

W ITH the developm mercial motor vehicle to the point where the figuring of maintenance ex-pense is an exact science, attention quire naturally centers around devices that are calculated to reduce idle time by facilitat lng loading and unloading operations.
Unloading, of course, is simplified with the aid of dumping bodies, several representative types of which we lilustrated and described under date of April 26th. During the past twelve months large con-tractors, and, in particular, coal merchants, have in many cases supplemented chairs, have in many cases supplemented their motor truck equipment by the addi-tion of mechanical loaders, and the re-sults have been highly gratifying. One device of the kind is shown in the accompanying illustration in operation loading run of the mine bituminous coal on a motor truck.

The machine is one of several quite similar types that have been developed atming types that have been overly need although the Aussauss are seen as specifically for this kind of work, and as with the auto (but would not be if the may be seen by the picture it is essent United States Army officials were within a may be seen by the picture it is essen-tially a bucket and a chaln conveyor; the elevating gear may be operated either by not only in the economy of first costs, our elevating gent may on operates some size of the date in the fact that it uses very little fuel an electric motor, when a source of currer of the vehicle illustrated can make from cylinder gasoline engine; in the machine forty to forty-five miles on a gailon of illustrated, a zasoline motor is used, and

vating gear consists of two six tachable link belt, to which 18-inch inch malleable iron buckets are at regular intervals; the wh steel truck, the larger wheels of 4 are 60 inches in diameter and the su wheels 20 inches. The machine weighs nearly 5,000 pounds, but two have no difficulty in moving it over h level ground. In some cases the madi are made to be moved by their own po In operation, one man is required look after the loader and to operate The clutch lever which controls the mo The citted lever wated controls the am ment of the buckets is not visible in; pleture, as it is on the other side of machine. After the driver of the tr has placed his vehicle in position un

the chute, both men push coal to the fool of the elevator for a few moments. When the truck is nearly filled, the driver moves it forward in order to fill all parts of the vehicle evenly, and trims the load. Unde service conditions, a two-ton truck has been loaded with chestnut or smaller elast anthracite in less than five minutes; egg and stove coal are loaded in from six to and acove coal are loaded in from an we eight minutes. A special type of loader (illustrated) loads a two-ton truck with bituminous run of the mine or small an-thracite in about two minutes or a five-ten truck in five minutes. As a matter of truck in new minutes. As a matter of fact, it has been found that the machine handles bituminous coal, which lies at a steeper angle than does anthracite and therefore slides down in larger quantities, therefore sinces down in larger quantities, so quickly that it does not pay to have the driver leave his truck; he study! trims the load. The foot of the bucket elevator is movable and the distance from the ground can be changed quickly by means of a crank which operates a worm gear keyed to a shaft which winds or unwinds chains attached to the foot. A fric-tion cintch allows the load to be thrown on after the motor has been started; by means of an extension from the cintch lever, control of the elevating gear is placed in the hands of the driger and it frequently is possible for the driver to operate the machine to load bituminous coal without help. The capacity of the machine is estimated at 60 tons of coal an hour provided a sufficient supply is kept under the foot of the elevato power required to operate it is five !

## Field Kitchens of the N. G. N. Y.

To the Editor of the Scientific American: In your issue of May Slat, 1913, is an article on a Russian auto field kitchen. Although the Russians are ahead of us mile of being up-to-date), I think that the Seventy-first Regiment, N. G. N. Y., was the first to practically use the field kitchen for feeding troops in the field buring the Connecticut maneuvers of 12th, three field kitchens were used, and the Seventy-first Regiment was fed reguiarly and well, white without an excep-tion the infantry regiments under United States Army methods were without food volunteer troops, which or always have to depend up-possible disputes with some ere and the fathering of the parenteet in the party those 1995, this may be all leggle vis. Construct from page 26.1 to largestry his industry, his careful-ness, this conscientions accounter, and many other such consiste cannot be de-termined by an observation of any one of these into elements alone, but can be unertingly appraised by careful obser-vation and analysis of the proportion in high the nine elements are con

It is abundantly clear, from the fore sing, that the character analyst who attempted to judge of the qualifications of any applicant for a position merely becaus he was of fine texture and blonde com ne was or nue texture and blondo com-plexion, would go as far wrong as a chem-ist who analysed a carbohydrate quan-titatively for carbon and hydrogen, but neglected to do more than determine the tweepen of overen

or and olive oil have approximately the same proportion each of car-bon and hydrogen, but because of a very slight difference in proportion of oxygen. and in the manner of their combination, one is aromatic, strong to the taste, and poisonous; the other is mild, soothing, and nourishing. So two men may be almost exact counter-parts of each other in texture, size, form, color and consistency, but on account of a difference in proportion. anions, and experience, one will be a lagy, shiftless, careless, irresponsible burupon society, and the other a su

It is well known that certain chemicals unite to form useful substances, and that others units to form sither pusions of actually explosive and destructive substances. It is also well known that ceren seem to co-operate and harmon ise with one another most efficiently, and that certain other men cannot be as ated together without inharmon, more of

Just as chemical analysis enables the experienced chemist to determine which experienced chemist to determine which chemicals he desired to mingle in order to obtain desired results, so the experi-enced ambyst of human character has learned how to associate different types of executives and employees to secure the greatest efficiency.

It is evident that a man or w out unusual gifts can study signs based upon the foregoing nine principles, learn the meaning of their compounds, and become skilled in the selection of men and women for their fitness for functions in an organization the requirements for which have been carefully pre-fetermined.

That this can be done is demonstrated by the success of employment departments installed by Dr. Blackford, and conducted

The conclusions reached by Dr. Blackspeedily and strikingly verified.

When the employment plan was first installed in a certain factory where many electric cranes were in use, and before there had been time to analyse fully the requirements of all the different classes of work, a requisition was received by the employment department for ten crans operators and twelve crane hookers. The assistant who received the requisition telephoned the superintendent to inquire something about the work to be done, and the qualifications necessary for its efficient performance.

ong other things, the superintendent said: "This work is rather danger his fellow workmen seriously injured or killed, so send me men who are very careful."

With this instruction in mind the sastet ant analysed a number of applicants, and from them selected fifteen—the fifteen who, with other requirements, were nat-

from these selected fifteen—the fifteen who, with other requirements, were naturally the most cautious and careful.

Not one of the fifteen, when his prosective duties were explained to him, by the superintendent, would take the jost this offices. ## The Wire Industry

STATISTICS for the wire industry in the United States for 1909 are precented in detail in a bulletin soon to be issued by Director Harris of the Bureau of the Census, Department of Commerce it was prepared under the supervision of William M. Steuart, chief statistician for manufactures

The manufacture of wire in the Unite States is carried on by three classes of ents: (1) Establishments whose principal business is the drawing of wire from rods which are either purchased or transferred from independently operated rading milis of the company, thus includ-ing the detached and independently oper-ated wire milis of companies rolling the wire rods; (2) establishments that roll from and steel, copper or other metals or alloys and maintain wire-drawing departments supplied with rods from the co-operating iolling mills; and (3) establishments whose principal business is the manufacture of some quite different product, but which incidentally draw some wire usually as material for their own con-

There are many establishments which draw no wire, but which manufacture wire goods (fencing, wire cloth, springs (c.) from purchased wire. Such estat lishments are not covered by the censu statistics for the wire industry.

The total number of establishin the United States in the wire industry as whole in 1909 was 93, of which 56 w wire-drawing mills proper which pur chased the wire rods used, 31 were wire departments of rolling mills, and 6 were wire departments of other concerns

The total value of the products of th 13 mills or wire departments was \$180,-083,522, of which \$173,349,014 consisted of wire and products derived therefrom Of this latter amount, 45.7 per cent rep ented the value of products of the wire milis and 50.8 per cent that of the wire departments of rolling mills.

Data regarding the wire industry as at entirety are not available for 1904 and 1809, but an approximate idea of its growth may be gained from the statistics of the production of wire rods of iron and steel. The output of such wire rods in 1899 was 916,587 long tons; in 1904, 1,792.-704 long tons, and in 1909, 2,295,279 long tons, the increase for the decade being 150.4 per cent.

The large plants predominate, especially among the wire departments of rolling mills. The 24 wire departments of rolling mills whose product exceeded \$1,000, 000 in value together contributed \$89, 407,015, or almost one half of the tota of products of the industry.

Of the 93 establishments in the indu in 1909, 59 drew iron and steel wire exclusively, 7 drew copper wire exclusively, 6 drew wire from materials (chief brass) other than from and steel copper, while 21 drew wire from two or more of the metals. A large proportion the establishments manufactured wir natis, barbed wire, woven wire, and othe icts for which plain wire is the prin cipal material.

Of the total expen s reported by wir of the total expenses reputed by man-nills in 1909, satarles represented 2.8 per cent; wages, 13.3 per cent; cost of mate-rials, 78.2 per cent; and miscellaneous exenses, 5.7 per cent.

The cost of materials in 1909 repr ed 71.7 per cent of the total value of pro-ducts, and the value added by manufacture, 28.8 per cent.

The total number of persons engaged in whre mills in 1909 (not including the wire departments of rolling mills) was 19,945, of whom 18,084, or 90.7 per cent, were

life-boat track which extends from the d down alongside the vessel to the water line and is so supported that it may be swung on extending transver from the vessel to one lying against the side of the vessel.

## French Fisheries on the Newfound land Banks

T WO recent consular reports from St Pierre call attention to the many in teresting and unique features of the Brench fisheries on the Newfoundland Banks. This industry is more than 400 years old, and has changed but little with the progress of the centuries. The only ortant innovation was the substitution of light deries for the clumsy "chaloup in use prior to 1865. It is true that with-in the past five years the steam trawler in the past my years the seam travies has appeared as a rival, but not yet a dangerous rival, of the brig and schooner. In 1912, 240 vessels and 6,888 men en-

gaged in the Banks fisheries constituted what is known as the "metropolitan fleet, i. e., vessels fitted out in Normandy and Brittany. These vessels leave France in late March or early April and require from 14 to 45 days for the passage, according to wind and weather. The voycording to wind and weather. The voy-age is perilous, for the craft are very small and the methods of navigation are of the simplest. The masters of these vessels take observations for latitude, but have no chronometers and cannot deter-mine their longitude with any accuracy. On the outward journey they can tell roughly from soundings when they have arrived at the Banks; returning they can estimate their position when they cross the steamer lanes converging toward the English Channel. Besides the metropolitan fleet, a cer-

tain number of vessels (40 in 1912) are fitted out in the colony of St. Pierre and Miquelou and manned with Normans and herefore and manner with normans and Herefore who come out in the spring or a steamer chartered for the purpose and return to France at the end of the season Formerly these men made the journey in stilling resents, which were often danger-ously crowded. The combined fleet in 1912 numbered 7.500 fishermen

The fishermen do not work for wage out for a share in the catch. Before they leave France they receive an advance payment, varying from \$75 to \$150, to be deducted from their future earnings. If, as not infrequently happens, a man's share at the end of the season is not sufficient to cover the amount advanced to him, the owner of the vessel loses the difference, and the man himself comes homwith empty pockets. The fisherman's total earnings in seven months of hard labor and exposure probably do not aver-age more than \$150. Strangely enough, age more than \$100. Strangery enough, the men appear to be content with their lot, and all the reforms that have been effected toward improving their wages and the conditions under which they labor have been initiated by naval officers, administrative officials, culliphened ship-may be the second of the second of the Science of the Sc owners, and persons engaged in the Sc ciété des Oeuvres de Mer.

## The American Mining Congress

MANUFACTURERS of mining machin-ery, rescue and first ald apparatus and safety appliances are to be given an and safety appriances are to be given an opportunity to display their wares before the mining men of the country at a great industrial exposition to be held under the auspices of the American Mining Con gress, in Philadelphia, Pa., the week of October 20th.

This exposition, the first of its kind in this country, will be held in conju with the annual convention of the Mining perted to attract thousands of interested pected to attract thousands of interested men. It will be entirely national in scope, the motal mining interests of the West to be as fully represented as the coal sub-ing of the East. ## Cadillac leadership in scientific motor car development is once more strikingly demonstrated

A new quality of luxury

A new element of efficiency

A new source of economy

Each year you have looked to the Cadillac for the real and substantial progress in motor car development.

You have looked to the Cadillac for the great essentials in the practical motor car.

And you have not looked in vain.

Now conceive, if you can, a Cadillac with its essential functions sharpened, accentuated and refined.

Conceive such a process of refinement culminating in an entirely new riding quality of unexampled ease.

That is precisely what has come to pass in this new car.

The principal contributing factor—the two speed direct drive axle—is described in detail elsewhere.

The Cadillac Delco electrical system of automatic cranking, lighting and ignition, the first practical system ever made and first introduced by us, has, after experience with it on 27,000 Cadillacs, been still further

developed, improved and simplified and the slight attention required from the user materially reduced.

The carburetor has been improved, its efficiency and its well-known economy increased. It is not water jacketed and electrically heated to facilitate starting in cold weather.

The rear springs are six inches longer.

The body designs are new and strikingly handsome. Front seat passengers may enter or leave the car at

either side.

These and many other refinements of essential details make for a greater and a better Cadillac and serve to more firmly establish its position as America's

leading motor car.

The Cadillac Company has never disappointed you in the smallest particular or in a single promise.

We promise you again, in this new car, a positive revelation in motor car luxury.

## Cadillac two-speed direct drive axle

The advantages of this ask do not lie in its being an Improvement to far its functions as an usit are voucerated by rather in the mailfold advantages attained to other directions through the medium of the ask and the second of the second of

## Torpedo Tubes But No Torpedoe

TRLIC attention has main been directed to the very serious insufficiency of the torpedo supply of our Navy. Congressman Britten, a memor of the House Naval Committee, has recently stated that if war were begun to-morrow, we would be in a sorry plight so far as torpedo defense is concern some of the torpedo bont destroyers in commission carrying only sufficient torpedoes on loard to fire one round from their tubes. Again, Capt. Sims of the Navy has recently stated that, although there has be pended about \$50,000,000 on our present fleet of destroyers and submarines, we have not more than one torpedo for each tabe; and the same authority tells us that the situation, in the event of a serious war, would ere similar to that of an army marching to battle with one cartridge in each soldier's rifle, or a fleet steaming to meet the enemy with one projectile for each of its guns

Now in the face of this shortage-und it has be known now for several years, known in every mavy of the world-it should be one of the first acts of Cor gress to make the appropriations accessary for doubling the capacity of the naval torpedo factors at Newsort. and for the immediate purchase of torpedoes in s cient numbers to bring our supply on hand up to the required standard. At present, we have about 1,000 torpedoes on hand, whereas the principal foreign navtes, according to Cupt. Sims, have from 6,000 to 10,000 very member of Congress, he he big-navy or little-navy, battleship or no-battleship to bis attitude will realize that the first thing to do and the least that can be done, is to make an carty appropriation to bring such battleships, torpedo boats and submarines, as already possess, up to their full fighting efficiency.

## Another Call for the Fireproof Stairway

IAGHTED eigarette, un abuudance of combus the fabric, and a first-rap stativary, appear to have been the contributory causes of another fre-horror-this time at Binghamton, New With the appeals of the victims of the Triangle fire to this city still in the public ears, there come the eries of over half a hundred girl victims of another fire, calling for stern legislative action to render a further repetition of such a ghirstly disaster impossible.

When the fire broke out, there was a certain amount

of panic of course; there always will be in a factory In the construction of such hulldings this fact should always be kept in view. The means of egress should be umple, and those for descent to the street, whether by elevator or statrwny, or both, should be such that when the inmates of any floor have made their escape from the main building. they will be sure of gaining the ground in safety.

Now the only sure way to seeme these conditions, as

we pointed out after the Triangle fire, and many times in years preceding that disaster, would be to construct both elevators and stairways, or at least the stairways in a separate fireproof shaft or well, built exterior to the mulu wall and having no direct openings from itself the mini wan and naving to direct openings from their to the various floors. The complete exclusion of dame and smoke from the stairway would be secured by placing the doors leading to the stairway at the various

floors, outside the stairway shaft, with concrete or iron platforms leading from the main building to these doorways. A firsproof, inclosed stairway of this character, built external to the main walls of the factory, would have reduced the terrible list of fatalities at Singham ton and possibly would have enabled every issuate to

escape.

The majority of the so-called fireproof stairways in existing buildings are such only in name. To build a stairway of incombustible material is not sufficient to render it fireproof in the sense that it will present to request to report in the sense that it will peecent as as fee means of exit from the building. A stalway is fireproof in this sense only if the construction is such as to exclude the sufficient games, which are the most fruitful cause of death in conflagrations. It should be better understood than it is that of the people killed in fires, the great majority die, not by actual contact with the fiames, but through suffocation by inhaling the products of combustion. A notable case of as the fire about ten years ago in the Park Avenue Hotel, this city, in which the majority of the vic-tims were not even scorched by the fire. Now when the doors leading to the so-called fireproof stnirways, open directly from each floor onto that stairway, the latter is timble to serve merely as a big vertical flue, which, when the doors are opened, is liable to draw the smoke and gases into itself, and render the stairway impassable, except at risk of quick suffocation. In son of the latest buildings such stairway wells, entered from the outside of the building, are built within the from the outside or the duffering, are built within the building lines. The better and safer construction is to form the well outside of the building; this for the rea-son that the entrances at the different levels are farther removed from the rising columns of smoke and gases.

## Vitalism and Mechanism

THE camp of biologists is divided. There are those who hold that the phenomena of life involve a separate principle which does not operate in non-living matter. Another school seeks to interpret all actions or functions of the living organisms in term of the general laws of nature which to all matter living or dead.

To us it appears premature to take any side in this dispute. There is a very wise principle current among scientific men, that the aid of a new hypothesis shall scientific men, that the and or a new mypornesis somit not be invoked, so long as a given set of phenomena can be explained without it. It is therefore clearly the best policy in the investigation of life phenomena, to press forward as far as we can by the application of the methods and principles with which we are familiar in the physical world in general, and to see just how much of the renarkable phenomena presented by living matter we can explain in terms of such general laws, matter we can explain in terms of such general laws, before we attack the question whether, after all his been done in the way indicated, there still remains a certain reddam of facts which cannot be accounted for in this way, and for the explanation of which we must justifies some special "vital principle" or what-ever we may like to call it. This course is christonic from four may be called the state of the course of christonic free from any possible objection. It denies nothing It makes no assertions as to what can or cannot be It proposes simply to continue work along lines which have proved most fruitful in other direction and which have begun to bear very valuable fruit in the special field of blology also,

The work of 1rof. Leduc may to some appear to have fittle bearing upon life phenomena. His adversar nave intro ogering upon me passionena. It is adversar-ies may see in his experiments a mere accidental re-semblance to certain appearances observed in the living world. While this criticism may possibly not be sito-getter unfounded as regards some of his experiments, tn the case of others the burden of proof lies heavily upon the critics. And in any case, the work of Leduc will have furnished interesting and important data on

will have furnished interesting and important data on hydred questions, even if we utterly diverged its pos-sible or probable bearing upon life phenomena. Upon another page we bring in this lesue a review of 1 rof Ledne's work "Synthetic Biology," and some additional data of his researches with be found in this week's lesue of the Selectives American Supplement. The French savant's investigations relate more parties tarty to effects observed in the purely physical world, resembling and, in Leduc's ordinion, identical with the phenomenon which biologists have termed chemotaxis. This term is employed to designate the property pos-This term is compayed to temporate the property pos-sessed by certain organisms of being attracted or re-pelled by certain chemical substances introduced into the water in which such organisms are floating freely.

To the nalve observer these organisms appear to be guided by some sort of intelligence to seek out certain materials and to shun others. To ascribe in to lowly organisms of this character is in itself a very doubtful proceeding. It becomes still more doubtful when it is shown, as brought out most clearly in Prof. need to shows, as brought out most clearly in Frot. Ledic's work, that precisely the same faind of behavior is displayed by purely inorganic substances. Particu-larly instructive is an experiment described by the French biologist, in which a roll which has been dipped in alcohol is breagate to writing a termine of a from the surface of water consisting a seek of ink. The vapor of the alcohol cases in contact the water and cases the India, the of the same the point affected. To express surface point affected. To express surface point affected. To express surface for surface might be said that the India has "seek" in a

## An Epochal Achievement in the Electrical Arts

NE of the latest, and certainly one of the most important applications of electricity to the dustrial arts, is the use of the electric ours

for the refining of sices in large commercial quantifies such as are called for by the beavy riseds. This do no improvement whose far-reaching importance has inhibato been appreciated only by those which are interested in the theory and practice of sied 'minuthippes. The introduction of the Reseauer converter make it possible to manufacture steel in large quantificities at a low cost, and laid the foundation of the special ties at a low cost, and laid the foundation of the special form the time when the Beassens' converter was made a practical success flown to the present day, the principal efforts of the special palace have been directled to removing certain impairities and defloral which are inseparable from the Beassens' possess. The Blemsmartin open-hearth furnace was the first successful. marin open-neurn rurance was the nryt successful competitor on a large scale with the Resement converter, and the open-hearth treatment has sendered it possible to turn out steel in equal quantities, of a superior purity, and for a signify greater cost than by the older method. . ..

There has always been a market for a special steel casessing in the highest degree the purity, homogen eous structure, and relative hardness and toughness, which are necessary when steel is to be subjected to which are necessary when steel his to be subjected to the most severe mass, and for bandy deededs a limited sincent of such steel has been made by what is known as the crucible process. But this process has always been and is to-day a coetty one, and its product is coverently and if it output to limited, as to reader life wholesale use for the production of chasp steel such as used for rails, bridge work and in the bearier steel such trades, quite out of the question,

arching for some new method that would combine the capacity of the converter and the open-hearth furnace with the purity of the product of the crucible, it was inevitable that the thoughts of the steel maker ould turn to the electric current; and over thirt; years ago Slemens made some practical experiments on a small scale, by which he succeeded in making limited years ago Nieunens made some practical experiments on a small scale, by which is succeeded in making limited quantities of steel baying, per of the electric arc. The very littereding development of his lawention, as sketched out elsewhere in this issue, shows that the suc-cess of this method on a commercial scale was merely a question of the progress of electric eighteering. This development has been as markle, and the results already achieved are so fail of promise, that the introduction of the electrical refluing of steel can be said to mark an exact in the history of the art, measurable in im-portance to the advent of the Bessemer converter and the open-hearth furnace. During a single decade electric refluing furnace has increas ed in capacity from two or three tons to thirty tons, and the present anumal output has reached in round numbers about 1,800,000

The significance of these figures can scarcely be over-The significance of these figures can scarceap no over-crimated. They mean that the day is within sight when, at a cost not very much greater than the present cost of Bessener and open-hearth rails, after fails, for instance, will be supplied which will possess the wear-ing qualities and the toughness to enable thep to stend up under the heavy wheel loads of American traffic.

even during the low tagniferatures of the winter season.

For the present, electrically reduced steal, though far,
cheaper than crucible steel, will of course be considerroot to breast, executasity remark steel, though far chespor than cruellies steel, will of course be considerably dearer than Bessesser and open-hearth. The promise of the future as reparts the levistics of the cost of the new steel lies in the fact that is the sperition of the Herouti fraincas, which bids fair to gain exclusive control of the field, there is still important economic fact, that the larger the furnasce the less is the cost of reduing. Furthermore, there is mobility in the construction or principles of operations of this time account fact, that the larger the furnasce is a local to the large open-hearth furnasces. All 500 ton capacity move in usa. There are electrical-steel furnasces of 115 fain capacity working successfully in this popular, and others of 35 tons are planned. In Germany 30-ion furnasces, also within a few years' time, thanks to this deared application of the second original, and of the very highest quality will be averable as appointed seek and in any decisived quantity.

## Electricity

The Condenser Telephena.—The inventors Ort and Riegar are quite successful in their work on the concense telephones, having taken up the question in Germany with the idea of improving the results obtained by the method, and were able to preduce excellant telephone receiver, it is said. They first made leat telephone receivers, it is said. They first made use of a condenser made up of sheets of tissue paper treated with shellae and covered with throtil so as to torm a 0.05 microfarad condenser, and when used on the receiving and of a telephone line they found that it vibrated quite like a receiver and delivered articu-late speech under better conditions than herstofror. A still better makeup was of thin membranes of rubber stretched drumwise and covered with vary thin films of alterniquem as the sea 0.00012 inch, the thickness of or autemptum as in as a COUCH inch, the thickness of the rubber being about the same. Even greater success was now obtained, and the inventors state that the condanser vibrates as well as the common telephone receiver and even better, and gives clearer speech than has hitherto been obtained.

"Sillie."—A composition which the German inventor Dr. Egly calls "sillio" is said to be an excellent material for making up electric heating resistance pieces and the like. It is a compound of silicon and silicon carbide, and answers to all the requirements, for it is not injured by the heat and at the same time conducts the current, being also compact and substantial, and can be molded in any shaps. "Sillio" is not attacked by saids nor affected by expansion and contraction under best. The inventor tried cachorundum and silundum with most of the contraction The inventor tried carborundum and silundum with-out success, then he found the present method, which consists in mixing silicon carbide with silicon and a suitable binding material, heating the mixture and then giving it a final treatment in the electric furnace. then giving it a final treatment in the electric furnace. In this way he obtains any desired modeled shapes in a homogeneous and non-porous substance. As it is a conductor of current, it can be used to make up electric heaters of various shapes. Another use is for the obtained of the controllers, and the inventor finds that tubes up to three inches inside disanseer will come to a high heat when under current, so that they serve for wire-treating furnaces or for tempering steel springs, such tubes being very durable.

Portable Wireless of Tuning-fork Type. retuble wireless of luming-tora 1995.—Inc racine engineer H. Magunna, whose work with the late Prof. Mercadier in vibratory multiplex telegraphy is well known, now brings out a system of portable wireless known, now brings out a system of portable wireless outlite for military use in which he employs a new musical spark method. This consists in the use of tuning forks which break the 220-voit current at a constant rate of 750 vibrations, and a rather original method is used to keep up the vibration of the forks: for instead of using electro-magnets, which have some directions of the constant of t motor to drive an endless belt stretched between two pulleys so as to run continuously, and the sharp angle of one prong of the fork is presented to the belt surface so as to keep the fork in vibration by this purely me-chanical means. The fork, the transformer primary and the telegraph key are mounted on the circuit of a small dynamo, using a condenser to suppress the sperk, and the frequency of the current thus obtained is quite constant at the same rate as the fork and is independent constant at the same rate as the fork and is independent of the dynamo speed. He makes up very light portable wireless plants on the musical system, for aeroplanes and airchips, army field use, fishing boats and the like. One box contains the 1½ horse-power gasoline motor and small dynamo, and another the tuning fork ap-

Hydraulic Power Plants in Calabria, .-- Southern Italy is to secure a large amount of hydraulic power in the Calabria region for operating electric plants, and it is to sesure a large amount of hydraulic power in the Calabriar spoin for operating electric plants, and it is expected to lay out water storage reservoirs so as to obtain 50,000 horse-power. The fills mountain region has an abundant rainfall, but this is quite irregular during the year, for some streams which are torrents in winter are nearly dry in the summer season. In order to regulariste the flow there will be used four great reservoirs, the largest of which will contain 5,000 million cubic fest of water. At the start, there will be exceted a 50,000 horse-power turbine electric plant, and part of the oursent is to serve the interact of calcium tertilizer works, the resistanter to be sent over long power lines through Calabries and neighboring regions. Agriculture as well as liggions will profit by the new enterprise, as through the sum of the start, and the sent over land and the country will have a realonal trigation system, origing to the regular, water supply. Sardinia is to have a somewhat similar sobame before long, and at its inland is expensibly devoted to horse and stook eating, it is expected, that the quality of fodder will no longer eight during the largest plain. Numerous mines will impose the Calabrie plain. Numerous mines will impose the Samuel Sing prove Instead of expensive will impose the sense of the

## Aeronautics

The Wilbur Wright Fund .-- Horace Darwin, former Mayor of Cambridge, England, and a member of the Advisory Committee for Aeronautics, delivered a lecture on May 21st in aid of the fund to build a memorial to Wilbur Wright.

The "Record" Altitude for Captive Balloons was attained at the Lindenberg Observatory on February 20th, 1913, when three of these balloons were sent up to a height of 7,180 meters above sea-level (23,556 feet, or about 4½ miles). This is a little less than the "record" altitude for a kite (23,826 feet, at Mt. Weather, Va., May

A French Aeronautic School .- The school of aero-A Franch Aeronautic School.—The school of aero-nautics and mechanical construction which was founded at Pars a few years ago is now in very successful operation and is well attended. It is of an industrial character, and is intended to turn out eigineers for the mechanical industries in general, and more especially for the branches of aeronautics, automobile and allied industries. Entry to the school is determined by competitive examination, and to prepare for this there is instituted a prepara-tory course in a separate school. tory course in a separate school.

Natural Gas for Balloons.—We are informed by Prof. F. DeR. Furman of Stevens Institute that one of the graduates of Stevens recently made a little pleasure trip in a balloon inflated with natural gas. The pleasure trip in a dealoon innated with natural gas. The ascent took place at Akron, Ohio, and was the first ascent in a regular touring balloon ever made from that town. So successful was the trip that there is a chance of forming a small acro club in Akron to make regular ascensions at a cost probably not exceeding \$10 per passenger. The pilot of the balloon was R. H. Upson.

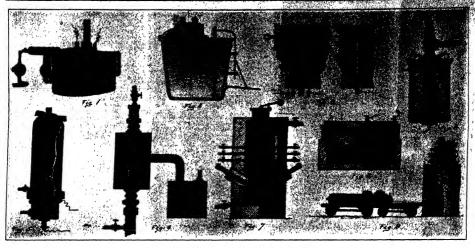

Making the Aeronautic Engine Non-gyroscopic,— William Phillip Holzmark of St. Louis, Mo., assignor of one half to Isaae Holzmark of vanne place, in patent No. 1,060,097, describes a non-gyroscopic engine in which two reversely running engines have a series of axially alined crank shaft sections with a reversing gear which permits one of said sections to rotate in one direction while the adjoining section rotates in a reverse direction and a single propeller is connected to one of the sections in such manner as to be driven simultaneously by both of the reversely running englues.

Dr. Beil and Transatiantic Flight .- Dr. Alexander Graham Bell recently announced that F. C. Baldwin, one of his assistants, seriously thinks of crossing the Atlantic in an aeroplane, in an effort to win the British \$50,000 prize. According to the newspapers, Dr. prize. According to the newspapers, Dr. oses that the flight be made at an altitude Bell prop Bell proposes that the flight be made at an altitude of five miles, where one thrut the density of normal atmosphere would permit a great speed. However the altitude record held by Legazueux, is only 17,878 feet, which means that Baldwin will have to go about 8,500 feet higher. There is trouble enough with motors, not to meution the luman breathing apparatus at a height of three miles

a height of three miles

A Parseval Dirigible for the British Navy.—A
Parseval arabilp constructed in Germany for the
British navy has been accepted by the Admiralty
Air Department. The vosed is the inneteenth constructed by the Parseval Company. The present
airship is designated as "P. L. 18," the first of the
series which came out in 1966 being regarded purely
as an experiment. The new British Parseval has
two Maylasch engines of 180 horse-power each, which
drive two four-bladed propellers. The newtope has
a capacity of 310,740 cubic feet, consequently the
coast is nearly 130,000 cube feet larger than the
existing army airship "Delta." The length of the
vessel is 275 feet and its greatest disaureter fortymiss feet. The fabric is treated with alumnium. At The fabric is treated with alummum. At feet. its first trial the airship is said to have developed a speed of 42.4 miles an hour. The lifting capacity is nearly three tons, exclusive of its own weight.

The Dynamic Meter is, according to international agreement, the unit hereafter to be employed in aerological tables and discussions in expressing altiservingness tables and dissussions in expressing sittude. The need of replacing geometrical by dynamic attitudes in dynamic meteorology depends upon the fact that the force of gravity is not the same in different latitudes. In studying atmospheric movedifferent latitudes. In studying atmospherie move-ments it is desirable that the system of coordinates adopted should include planes at every point of which the force of gravity is equal, so that the work required to transport a mass of air from one plane required to transport a mass of air from one plane to another against gravity is always the same. The dynamic meter is defined as a vertical distance cor-responding to 100,000 C. G. S. units of gravity potential and is equivalent, on an average, to 1.02 ordinary meters. The name of this unit, which is one of several new terms proposed by Prof. Bjerknes, has aroused much criticism.

Recent applications of the electric furnace in the industrial arts.

## Some Recent Improvements in the Use of the Electric Furnace

## Novel Uses for the Electric Current in Industry

EVER since the classic experiments of Day in 1801 of drawing an arc between two pieces of charcoal, and showing the chormous heat that can be produced by the electric current, the use of electricity for the production of high temperatures has been a very powerful weapon in the hands of the scientist means then known for generating current were of the crudest type, and it was not until the Slemens dynamwas pinced upon the market that there was any possi-bility of the commercial use of the electric furnace. Current generated by means of steam cugines us prime movers was still too expensive and was unobtainable In burge enough committies to warrant extensive use The greatest impetus was received by the installation of large water cower stations such as the Niagara Falls plant, where current is obtainable at greatly reduced cost, and in almost any quantity. Under these favorable conditions the electric furnace has become a most useful and important factor in a great number of indu This in turn has faraished favorable amortual tles for inventors, and the last year has seen a con-siderable number of improvements in electric furnice es, as well as in the structure of the various types of furmices

the great field of work has been in the from and steel industry. This subject is frentled historically. In a separate article in this being; but we present herewith interactions of two of the latest patients taken out in the I mited States. The first of these is the scheme in the voiced by Albert E. Greene of Chicago, Fig. I (instead States), 1184-1874, and 1184-1875, which consists in maintaining the roundy blown steel as it first course from the converter in a constant, predetermined temperature, and blowing through it is milking on cases that have the effect of coldibular out some of the impurities that it is desired to eliminate At the same time the modifier mass is subject to the action of a sing that flows of tow, which will dissolve out the other impurities on tow, which will dissolve out the other impurities.

A different process for obtaining partified Iron of a very nutform, unsity is due to William R. Walker of New York, Fig. 2 (1685,280). By this method the "microscopic sing" is more thoroughly removed and a better mixing of the constituents of the motien mass estatanced. The rough Iron is blown in a converter which has a "lastle" litting, and then is poured into a mixer, the litting of which is of a non-reld nature. Frum there it is poured into an electric furnace, the hing of which is of "nodi" nature. Here it is given the final partitiont and poured into a large mixing lade and from the mixing inde it is transferred to the journing or casting laddes. This is a continuous process and the products #85m several units are continuity exclanged, the result being a very uniform product.

phorus, and the slag on tup of the mass takes up the sulptur. The large mixing indic gives the finely divided slag u chance to separate out, as the Iron is still in a highly heated condition, which allows a longer and more thorough unification. The advantage of using the neid lining in the electric furnace is that the lining

lasts longer and is more easy to replace. Besides the steel industry the synthetic production nitrogen compounds, commonly known as "fixation" of nitrogen, is unother industry furnishing a great propect for the inventor. These pitragen compounds are need in making nitric acid, and further in making all kinds of fertilized compounds for agricultural pur-poses. The idea of combining the free nitrogen and poses. The mean of communing the free introgen and oxygen of the nimosphere has long been proposed, but the practical difficulties are munoanly great. Previously the chief difficulty appeared to be in obtaining a high enough temperature. The electric furnace has supplied this requisite; but another difficulty noneurs in the fact that the compounds at the temperature of formation are quite unstable and tend to break up just as fast as they are formed. If these gases can be couled immediately upon leaving the zone of formation, they may be preserved in a fairly stable state until they can be further combined. It is a difficult matter to cool the guess without at the same time cooling of the furnace, and thus wastlng a great deal of energy. The gases must be e to come uniformly in contact with the hottest part of the furnace, to obtain a uniform product. A number of inventors have attacked this problem with the view of putting out the arc and then striking it again, the interbut being used to cool off the gases. Heretofore this

Recently two French engineers, Bunet and Baden, Fig. 3 (nated No. 105,054), have devised a way of causing intermittent area, which is calmed to increase the efficiency of the apparatus to a marked desrree. As electrodes they use two conductors arranged like the terminals of the well known "ram's horn" elecult precisers for high voltage circuits. These electrodes may be merely two rods, or the one may take the force of a funnel with the other projecting up through; the center as a plain rod or plurality of rade. Air is blown up through the shortest part of the gap between the electrodes by means of a jet of rather high velocity. This of course tends to blow the arc up with it until the gap is so great that the arc can no league teap the gap and as a consequence it breaks. But the voltage of the circuit is great enough to cisse sisother arc to form at the lower end of the gap, where the distance is least. In fact, the investors claim that in

the top of the electrodes. From the top of the electrodes the combined gases are led directly into a spray of water or steam. The principle of the magnetic blow-out has also been used by the same inventors, to cause a rend succession of parts.

and to the different content of the commonly of the commonly. Another indexently method of fixation of nitrogen is the hierarchino of Joseph R. L. Brayden, Pig. 5 (patent No. 1.04)-211. A relevant part of the content of the content

But not only in these two great industries do we find the electric furnace useful, for a great number of miner industries owe their existence to, the electric furnace. For listance, the manufacture of, as for ligitime, heating, and industried purposes in accomplished by the dissociation of whom in the presence of carbon districts or a hydrogeneous and in pasts of purpose nearbon districts or a hydrogeneous and in pasts of purpose monophile is useful with pasts of purpose monophile is useful with pasts of purpose monophile is useful with pasts of purpose industries. The country of the hydrogeneous country of two hydrogeneous or country of the hydrogeneous or country or c

men the displaced recommend of a color can a pro-cess ("Not coulded" description that he are an electronic content the soft-efficient of which he provided with a which such all yellocarbon and the channel and envisor discribed on a light-occurbon that the sideal space for explaced the significant of the channel and the those coulded with the country of the sideal space of the sideal space of the composition of the sideal space of the sideal space of the sideal of the sideal space of the sideal space of the sideal space of the sideal space of the sideal description of the sideal space of the sideal of the sideal space of the sideal space of the sideal space of the sideal space of the sideal of the sideal space of the sideal space of the sideal of the sideal space of the sidea

a possibilities looks largely to the electric furnace. The natural rocks that bear phosphorus are difficult to break up and the tremendous heat of the electric furthe tremendous heat of the electric fur-nace is one of the most powerful means of breaking up these stable compounds. Such a process is practised in the fur-nace as shown by F. S. Washburn, Fig. 7 (patent No. 1044867). Carbonaccous material such as coke or ceal screenings is charged in with the rock and the charge is heated by the passage of the current therethrough. Air in restricted amounts is admitted and the phosphorus is dis-placed from the rock by the carbon and passes off mostly as the pentoxid of phos phorus. The process is continuous, as the furnace is of the magazine type. The inventor claims that by the use of his apparatus be can obtain as much as 90 per cent of the combined phosphorus. The product thus obtained can be utilised in a great variety of ways, such as in the

Another industry that has been aided by the introduction of the electric furnace is the introduction of the electric furnace is the glass industry. The case of control-ling the exact temperature is a great factor in the success of the furnace. In a pro-cess carried out by Marius Sauvageon of Paris, Fig. 8 (patent No. 1,082,362), the itself forms the resistance material The furnace is started by pouring in some neited giass which, as is well known, is meited giass watch, as in well slightly conductive when in the moiten condition. The current passing through the moiten mass furnishes the necessary heat to melt the charge of sand and soda that is used as the raw material. The melted glass flows out from under a barrier which serves to restrain the raw material from becoming mixed with the finished glass. Such a furnace is very pleasant for the workmen to handle, as the best is localized at the central point of the furnace just where it is no and the glass is withdrawn from the outer or cooler part. There is no danger of the workmen getting a shock, as the voitage

production of fertilizer and matches

A very peculiar and ingenious use to which the electric furnace has been put is described by Howard R. Connel (patent No. 1,023,229), whereby jewels for meters and cheap timepieces are made and fin-ished in almost complete form at one operation. A carbon block with some hemi-spherical depressions is arranged to form e holder of some powdered tungs Upon heating the block in an electric furnace the taugsten is fused and forms upon its outer part a carbide of taugsten, which is an extremely hard substance. In each sion is formed a small boat-shap

head just right for a jewel.

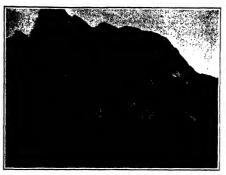

Another rather odd use to which the electric spark has been put is in a process for fumigation and killing of insects, Fig 90 (patent No. 1,037,744). Two tanks of gas, one of nitrogen and the other of scetylene, are arranged to discharge their contents in the proper amounts into a chamber which is traversed by a spark. Under the action of the spark the games unite to form hydrocyanic gas, which is very highly poisonous. When used to fumigate trees it is usual to inclose the tree in a tent and put the apparatus within the inclosed space. The control is effected by a switch some distance away.

Cutting Hair by Machine.—In patent No. 1,064,053, A. R. Coyle, Jr., of Traf-No. 1,004,053, A. R. Coyle, Jr., of Traf-ford, Peim, allows a half-cutting apparestus which is provided with outting blades op-erated by means of a vacuum and the vacuum slao serves to draw the haft to be out into the path of the blades or out-ters used delivers the out half to a suitable proposition.

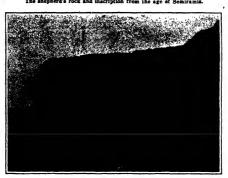

The Ballier of the Control

## e from the Land of Seniramis By Edgar J. Banks

SEMIRAMIS, the Oriental queen, who, until recently, S was supposed to have lived only in myth, has at last become a character in real history. Legend says she was the daughter of a fish godde miraculously fed by doves and reared by a si

The shepherd's rock and inscription from the age of Semiramis.

The Van castle wall, built in the time of Semiramis.

naine of a statue from the age of Semiramia

herd, that she was married to a governor of Ninevels, and won from him by King Ninus, that the king resigned to her his crown, that she built Babylon, and ruled Assyria for nearly half a century, that she was transformed into a dove, and was worshiped as a Becently, however, the German excavating to the old Assyrian capital city Assur has that one of the legends was true; she was really the wife of a king of Assyria.

Near one edge of the rains of Assur the Germans discovered a hundred or more tail stone monuments, monoliths from four eight feet high, standing side by side like gravestones in a cometery. Most of them were inscribed near the top with a few lines of ancient Assyrian cunciform writing. They were monuments erected in or of the kings and nobles of Assyria, and one of them bore the inscription of Semiramis, which, with one exception, is the only mention of a woman of high rank upon the monuments of Assyrin The in-scription reads: "The column of Sammuramat, the wife of the palace of Samsdadad, king of the world, king of Assyria, the mother of Adad-nirari, king of the world, king of Assyrin, . . ? of Shal-manusharid, king of the four regions."

ammuramat and Semiramis were one. Instead of twenty-two centuries B C . she lived about 750 B. C., and the fact that a monument was erected to her may indicate that she was really a queen, and one of the greatest of rulers

Her name to-day is still a common word in the more remote portious of the Turkish Empire, throughout all the region from old Armeniau capital, to ruins of Ninevell. Shamirum, as she is now called, must ut one time have been the ruler of all that country, for it is also filled with monuments associated with her name. Local tradition says that she was the queen of Van before she became wife of the king of Assyria. the Shamiram aqueduct which still brings water to the Armenian city. Upon the summit of a high hill near Van are the ruins of a rock-hewn fortress and of a temple attributed to her Scores of cuneiform inscriptions in the vicinity come om her time. In the very center of the city is a high rock surrounded by massive stone walls. Cut into its sides are long inscriptions and rock-hewn for resses and lace in which she is said to have lived Upon the summit are the ruins of a fortification. Recently, the Turkish soldiers, who are stationed on the summit of the rock, discovered among the ruins the er part of a large black stone statue Too heavy for them to carry away, or ignorant of its value, they left it there among the rubbish, where I found it. It is headless; the body is broken into tw parts: the feet, or the pedestal into which they were imbedded, have disappeared; the arms, bent at the elbows, are built into the body; in the lands are two imple-ments, probably the symbols of office, the as is a long tunic open in front with fringe along its edges. Though the head is missing, the hair was long; traces of it

still appear on the shoulders.

The date of the statue is certainly the same as of the rnins in which it was found, and of the inscriptions upon the rocks, or about 750 B C it comes from rocks, or about 750 B C It comes from the time and people of Semiramis, and though probably not of that queen, it is the only known Vannic statue, and as such, is of unusual historical interest. Research in this almost unknown land of ramis promises to restore the lost history, art and literature of the empire of this once supposed mythical queen.

## Fire Waste at the Conservation Congress

FIRE waste in the cities of the United States as allied to forest and water conservation will be given a prominent piace in the deliberations of the Fifth National Conservation Congress to be held in Washington in November Facts and figures emphasizing the tremendous loss caused by unnecessary fires will be laid before the congress by speakers of national note and means will be consider for the reduction of this vast waste.

## Fighting in the Air

By Carl Dienstback
THE German press was recently permitted to publish the results of tests in which many hundred rounds of ammunition were fired from a machine gun mounted on top of a Zeppelin airship in flight. As could be on top of a Zeppenn airsmp in night. As cound be foreseen from the absolutely stable nature of that gan platform and from the entire lack of vibration and swoying, these tests were almost as successful as they would have been had the gan been discharged at the

would make been and the kim been discensived at the dop of a mountain. The whiter speaks from experi-cace, having made tests in siming from the window of the cablin of the "Victoria Luise" in full light. These maching un trials were conducted to test an arbithy's shilly to defend listed against uncoplanes. The provious and the number of Fronch accoplanes made some such demonstration imperative during the political stress of the Baikun situation. The French seem to have attached little importance to the armament of the Zeppelius in view of the ever-increasing climbing powers of aeroplanes.

ropianes have recently reached altitudes, even with engers, that are still prohibitive to airships, except at the sacrifice of much gas and carrying capacity. dirigible's faster climbing is offset, it is argued, by the neroplane's ability to operate against the airship at a high level from the outset. Nothing prevents an aero-plane from doing much of its climbing at the start. Such was the lesson taught by the aviators who cross the Pyrenees and the Alps.

France aerial fighting is considered a climbing contest, a duel between two artificial birds of prey. As the aeroplane is sure to get on top of the le eventually, the latter's fate seems scaled in French eyes. It is, however, interesting to probe the question more deeply. Altitude appears a deciding factor because it is assumed that an aeroplane can, by superlor apeed, easily get in position to hover "motioniess trees tively) right above the airship and applicate it by merely dropping a bomb. The fallacy of this French reasoning rests on the comparative velocity of a ma chine gun's hullet and a dropping bomb's. In view of the airship's armament and the necessity for the aero-piane's flying with the same speed and in the same direction as the dirigible, in order to hit the quickly moving object, it is considered necessary that the bomb should be dropped from an elevation of no less than 2,000 feet above the airship. The calculations which permit an aeroplane while fiving across the ground to hit a target with a bomb by properly considering measuring its own speed relatively to the target and its distance from the ground, are no help ln aiming at an airship. Only the aeroplane's own velocity need be considered in fighting an enemy on the ground, but the relative speed between an airship with a motion of its own and an aeroplane (and also the vertical dis-tance) is such an indefinite quantity that no reasonable calculation can be based upon it. Nothing remained but to make use of the aeroplane's superior speed in obstinately hovering straight over the dirigible and "thus so far improving the aim that hitting became reasonably certain even at a vertical distance of 2,000

It remains to be seen how this theory works out in practice. The accuracy of the modern machine gun is such that in the opinion of military experts it does not anticiently scatter its bullets; it absolutely depends on having the correct range. In this respect a company of infantry is better than a Maxim. But precious ammunition must never be wasted in the air by scatter-ing the bullets, and "correct" range is "guaranteed," if the enemy can be hit point blank from a safe dis-

The invention of the steelclad "S bullet." pointed as sharply as an arrowhead, seems almost designed for aerial use. Indeed, it barely antedated the airwhip. It doubled the point-blank range which had already been pushed to 820 feet with the former blunt bullets At very high angles the point-blank range is again doubled. Therefore, an aeroplane is in peril at any point of an extensive zone around, and especially abo an armed Zeppelin. The latter's wonderful steading as a gun platform and the ever-increasing independence from range finding, uncertain in the air the higher the angle of fire, and the perfect accuracy of the mod-ern machine rifle are formidable factors that must be reckoned with. It goes without saying, that the gun on top of a Zeppelin will be intrusted to the crack shot of a regiment.

To use dropping bombs against such a weapon seems like a return to the medieval practice of pouring pails of boiling pitch. At a vertical range of two thousand feet, the distance of about seven streets, it would not require exceptional skill to hit an aeroplane, in its broadest aspect, which has to first an aeropanae, in its broaders was easier, which has to remain more or less stationary with reference to the dirigible if it is to use its bomb effectively. A bomb requires thirteen seconds to drop 2,000 feet. Thirteen seconds is time enough to evade an unwelcome visitor

In the clear air of the upper regions, a good pair of binoculars will enable a look-out on the steady dirigible to study in detail an aeroplane, "stationary" at 2,000 feet. The release of the bumb could no doubt be plainly seen (even in twilight with the help of the p archight now mounted on all big dirigibles) and an searchight now mounted on all big dirighoses) and an instantaneous electric signal to the helmstan will com-ple the strabily to turn. Running sixty-nine feet a so-cond, and, on account of the immense surface of the bull in proportion to the total weight, very quick to beep its rudder, it will be far from the point aimed at when the bomb at last arrivas. But the airship will hardly make it so easy for the aeroplane to remain vertically above it. It will surely turn and circle all the time the aeroplane is trying to get at it. This will not interfere with its own fire (a bullet travels 2,436 feet a second in a practically straight line at very high angles, only an insignificant adjustment of the sights to the known relative wind being required) but will hopelessly disconcert the aim of the man who is directing the aeroplane's bombs. For this there are several reasons. The eye alone can hardly determine several reasons. The eye alone can hardly determine whether the aeroplane is fifty feet out of a vertical line of 2,000. The suspended telescope used by Lleut. Sect for more exactly aiming bombs begins to oscillate and falls utterly in signag flight. A bomb released during a turn files wild, because centrifugal force does not allow it to drop vertically, and there is no way to ascertain the exact horizontal component of its traject-A bomb released between turns (if the airship should ever give such a chance to the aeroplane, which to stay right above it has to "copy" its every twist) is deflected because, after retardation by the turn, the airship's (and the aeropiane's) speed is not uniform, but accelerating. This, with the bomb's added retardation by the "relative" wind, is liable to drop the best almed bomb behind the airship. Finally, without an automatically vertical telescope, unaffected by irregular flight, and also the highest skill in steering, it is impossible to remain straight above the constantly

is impossible to remain straight above the constantly turning dirights. The task is further complicated by the need of maintaining stability in the wind, to which need the dirightle is not subjected.

The fact that light aeroplane bombs of small mass and large surface are always defected in passing through different wind strata, applies to all bomb work on aeroplanes. There is but one remedythe aeroplane's car, and getting nearer, even though it means destruction by the airship's explosion. But with means destruction by the airship's explosion. But with a machine gun it is possible to fell a tree. The wings, which cannot be armored, are vulnerable spots. Armor, moreover, will surely compet the use of small cannon in place of machine rifles. The use of small cannon will also be the eventual result of the attempts to arm aeroplanes with machine rifles. Fighting it out with firearms on both sides will be the natural end of the laced hawk-like tactics.

But if the airship mounts weapons which an aero-lane can also carry, it will, with its huge hulk, be at a disadvantage against a fleet of smaller aeroplanes. Naturally it must make good use of its capacity for mounting heavier pieces with longer range, and keep the aeroplanes at a safe distance. Then they will be shattered before their own weapons get into efficient range, because the heaviest cannon an airship can mount are almost as quick and handy as a rifle We can depend upon seeing cannon appear on the large dirigibles in strict accordance with the stage of deve ment of their adversaries, just as we saw machine gues appear, which are ample protection while aero-planes have no worse intention than flying over the airship and dropping bombs. Lowis Oliver, who flow over besleged Adrianople, anys: "It is no easy thing to regulate one's aim with bombs—I have tried it."

## What Are the Ten Greatest Inventions of Our Time, and Why?

## A Prize Article Contest Open to All Scientific American Renders

THE November Magazine Number of the Scientific American is to be devoted in part to a review of the A ALEMAN is to be devoted in part to a review of the great inventions of our time. Because a large number of Scientific Aleman readers are either inventors or users of inventions, it seems to the Editors that their judiment of the inventions produced in our time which deserve to be called the greatest, that appraisal of the relative importance of the paramount technical calcievements of our day, would be of peculiar values and interest. Therefore, it has been decided to leave the active mixture to them. the entire subject to them.

the entire subject to them.

The publishers of the Schenzupe American seffer three prizes of \$150, \$100 and \$50, respectively, for the three best articles on the topic. "What Are the Ten Greatest Inventions of Our Time, and Why?"

Contestants for the prize must observe the following

Each article must discuss and answer the fells

ing three questions:

a. What, in your estimation, are the ten greatest

The first of

inventions produced within the last twenty five years?

b. What are your reasons for this selection? Subtity your selection in each case.

TO STATE OF THE ST

c. To what person or persons is the greatest of due in the developing and perfecting of each inve which you have selected?

2. The entire subject must be covered in a type-written article not exceeding 2,000 words in length, and must be treated as simply, lucidly and non-techneally as possible.

3. In deciding what are the ten greatest invention of our time, the contestants are limited to machine devices and discoveries commercially introduced in the

last twenty-five years.

4. Since the SCIENTIFIC AMERICAN is "the weekly journal of practical information," and its readers practical business men and inventors, the articles submitted ld deal only with potentable inventions and dis-

5. In order to guide the contestant in deciding what is a great ploneer invention of our time, it is suggested that practical success and general usefulness to man-kind be used as a test. A modern discovery may have been suggested long ago and its underlying theory even worked out mathematically, as in the case of wireless telegraphy, but nevertheless it falls within "our time." telegraphy, but neverbletes it falls within "our time," if it has been made generally accessible and useful within the last twenty-five years. But commercial success should not be the sole criterion. The firing machine has not yet added millions to the machine has not yet added millions to the machine which but for all that, it is a great invention of our time. More improvements on well-known and successful devices are not to be numbered among the great invention of our time. Because an invention was first patented more than twenty-five years ago it is not necessarily debarred. The date of commercial far introduction not the date of the patent governs. The troduction not the date of the patent governs. The oreover, need not have been actually patented, but its subject matter must be of a patentable nature. Patentability is merely a test of commercial practicability.

stants must not disclose their identity. Each Conte 6. Contestants must not disclose their identity. Each article must be signed with an assumed name and must be accompanied with a sealed envelope, on which the assumed name is written, and in which the real name and address of the author is contained.

Contestants must address their articles, accompanied by the envelopes containing their real names, to "The Invention Contest Editor of the Scientific American, 361 Broadway, New York City."

8. The articles will be passed upon by a Board of Judges, whose names will be announced in a future issue of the Scientific American.

9. The Board of Judges will receive only the arti-

W. The Board of Judges will receive only the arti-cles submitted; the envelopes containing the true names and addresses of the authors will remain in the pos-essation of the Editors of the Schryttze Augusta. When the fudges have made their decision, the Editors will open the envelopes of the winning contestants and notify them of their success.

The decision of the judges will be announced in 10. The decision of the judges will be announced in the Schartific American of November 1st, 1913. The prise-winning articles will be published in the order of merit in consecutive issues of the Schertific American, beginning with the issue of November 1st, 1913.

The Editors of the Scientific American reserve 11. the right to publish in the SCIENTIFIC AMERICAN or the SCIENTIFIC AMERICAN SUPPLEMENT articles which have not been awarded prizes, but which are deemed worth; of hor le mention.

12. While contestants are not required to supply fetures with their articles, illustrations will be welcomed. If drawings are submitted, they need not be elaborate; the staff artists of the SCIENTIFIC AMERICAN will work them up for reproduction, provided the mais-rial supplied is intelligible. Do not send pictures torn from books and periodicals; they cannot always be reproduced authanctority, and their unauthorized re-production may constitute a copyright infringement. production may constitute a copyright maringement.
If photographs marked "copyright" are sent, they
should be accompanied with the copyright owner's written permission for their reproduction.

13. Members of the staff of Munn & Company, In-

rporated, publishers of the SCIENTIFIC AMERICAN, and of Munn & Company, solicitors of patents, are excluded from the contest.

All articles will be received up to 5 P. M., Sep tember 1st. 1918.

The Problem of Fuel in France.—The French Automobile Club lately decided to appoint a technical commission for the purpose of looking into the matter of finding a new liquid fuel for internal-combustion motors and also a sew figuid fuel for internal-combustion motors and also of increasing site economy of running engines with the present fuels. The commission is headed by the Princes of Arasistery and contains well-known technicians used. De Skyri, Chasseloup-Laubas, Fameschon and others. One of the questions which is being agitated of late in to provide is combustible of home predictions on as to be independent of other constraint, especially in one of war.

## Price Projection

To the Editor of the SCIENTIFIC AMBRICAN:
This company believes in the principle of retail
price maintenance because this is the best way to price maintenance decause time is the creat way to assure sheelute fairness to consumer, retailer and manufacturer. Such maintenance does not mean mon-opoly and expertence proves that well asstained prices on well-known and dependable products means lower

and fairer cost to the user on general products.

Unfortunately trade conditions have not permitted us to put this principle into practice in our own lines; but this does not change our desire to ac-

complish it whenever possible.

THE LOWN BROTHERS COMPANY,
Dayton, Ohio.

C. H. LOWE, Vice-Presider

## Price Cutting and Its Bad Effect

To the Editor of the SCIENTIFIC AMERICAN: To the Bidtior of the Scinswiss characters:
A desire having the exclusive squency for an advertised line of goods (unpatented) usually undertakes and of necessity does earry a suitable stook of such goods; and ase the manufacturer does not sell the same goods to sayons elses in the same etity, and does not himself sell goods direct to consumers at out prices, the dealer is thus assured of his leptifuncte outprices, the dealer is thus assured of his leptifuncte of the same control o

If, however, the manufacturer is compelled to sell other dealers in the same city, or is forbidden by law to fix the price at which the goods are to be sold, the dealer no longer has an incentive to carry a stock of goods, and in a short time it comes shout that no

the dealer no longer has an incentive to carry a stock of goods, and in a short time it comes about that no one in that city will carry a stock of goods because there is no profit in handling then.

The invariable desire of the masufacturer is to make the selling price to the public, especially of unpatented goods, as low as possible, fixing the profit of the dealer as small as the dealer can be satisfied with, in order that his goods may move freely: and the effect of an excritant price is always disastrous to both the manufacturer and dealer, because it tends to diminish the sale of the goods.

## Compulsory Licenses Under United States Patents

To the Editor of the SCIENTIFIC AMERICAN: One of the provisions of the Oldfield patent bill One of the provisions of the Oldfield pakent bill that is now before Congress is for the compulsory granting of licenses under patents that are not being adequately worked. In this connection, it is inter-esting to recall that England has had a similar pro-vision in operation since 1838. Under an act of that date, any person who could show that a patent was not being adequately worked in England, or that the not being adequately worked in England, or that the reasonable requirements of the public with repect to the invention covered by the patent were not being supplied, could compel the patent were not suit, to grant him a license to manufacture under the patent. From 1883 to 1997 only three suits were filled asking for such licenses, and once of these over proceeded to a hearing. Since 1897 a few suits have een brought, but generally speaking, there seem be a disinclination to invoke the privileges of law, due in some measure, no doubt, to the fact that a formal application for a license in such case would apparently carry with it an admission on the part of the applicant that the patent is valid and that the device he wishes to make is an infringement, and manu most cases, it is preferable to endeavor to evade the terms of the patent and let the patentee be the complainant in a suit, thereby placing the burden of the litigation on the patentee, and placing the manufacturer in a better position to negotiate a license by com-

A later act (1907) amplified the earlier law some A later act (1997) suspansed see outlined that the reasonable requirements of the public should be deemed not to be satisfied if any trade or industry is unfairly projudiced by the patenties trade or industry is unfairly projudiced by the patents on manufacturing the patented device to an adequate extent or supplying it or granting Bosses to manufacture it on reasonable terms, or by condition attached by the patentes to the purchase, restail, or use of the patented device. Still, in 1908 there was only one petition filed under this law, and that was withdrawn by agreement between the parties. The binds principles of patent jurispectations being the sense in this country as in England, it is reasonable to suppose that a law tills the above would be of 200 more use hope than is him growen to be in

Great Britain. A law that has been practically a dead letter in England since it was put on the statute hooks in 1883 is certainly of no value on the statute books of the United States.

MILTON TIBBETTS, Patent Counsel.

## Fixed Prices Protect the Consumer

To the Editor of the SCIENTIFIC AMERICAN: To the Editor of the SCIENTIFIC AMERICAN:
The manufacturer must say at what price the retaller shall sell his product, and the law must compel
the retailer to do this to prodect the consumer.
How? Because stores out prices on certain advertised

Hov? Because stores cut prices on certain advertised article to attract trade on other articles, scarding a sarticle to the profit on an advertised article to make it up on a raticle that yield an abnormal profit, i. e., a profit that will cover the loss on the advertised article cut. Therefore the consumer has been misled and deceived. The manufacturer's business has been injured, for other retailers who decire to sell his goods at a living profit will not handle an article which they cannot sell at full profit. full profit.

ould two manufacturers of a similar article get Should two manufacturers of a similar article get together and agree to sell their goods at the same figure, that would be an act in restraint of trade. But when one manufacturer seeks to fix his own price, other manu-facturers of the same thing may fix their prices a little if they wish to.

## The Danger of a Distributing Trust

To the Editor of the SCIENTIFIC AMERICAN: To the Editor of the Solishtype Alexicas: We believe that present American ignition and court decisions on price maintenance are made under a misapprehension of facts, and that the purposes which it is intended to accompilab by such activities will not be covered, but quite the reverse. All legislation along such lines has been advocated upon the ground that it would prevent monopoles and trust from having that it would prevent monopolies and trusts from having undue profits. As a matter of fact, these great organiza-tions will escape, because practically all of the great trusts have their own distribution. It will be the smaller concerns and those doing an honest and legit-mate business, attempting to do nothing except protect their customers from unfair competition and to main-tain the qualify and standard of their products, who will suffer. It will be impossible for any person having nown brand and reputation for quality to maintai a known brand and reputation for quality to maintain its quality if he is not allowed to protect the price at which such merchandise is resold. It will be used as a "football" and "extchpenny" by the great depart-ment stores and mail order houses, who ask nothing better than the opportunity to sell something of known standard for a less price than it can be sold at by any-body else, no matter whether they make a profit on it or not, in order to attract customers for less worthy

re is fast arising in the United Sta which it will be much more important for the Gov-ernment to control than the producing trusts. The most oppressive of all trusts would be a distributing most oppressive of all trusts would be a distributing trust, which would have control of and tyrannize over all small producers. This is a condition which is not a figment of the imagination, but it does to a certain degree already exist, and the smaller tradesmen, who perform a great service for the community, and who make their living chiefly from standard merchandise of known merit and of standard price, are to-day in anown ment and of mandard price, are to-day in ager of being run out of business by price cutting great department stores and mail order houses doing of great department stores and mail order houses doing a out-threat business. There are to-day in the United States fire dry goods retailers who each distribute over \$25,500,000 worth of merchandles a year, not to mention mail order houses that do a business cover-ing overything from barbed wire to a handkershief. The real menace of the United States to-day is price

titing, not price maintenance. Chever Brothers, South Manchester, Coun. By Horace B. Chever.

## Price Fixing and Competition

To the Editor of the Suneriro Augustain.

To the Editor of the Suneriro Augustain.

We are deeply interested in the question of maintaining uniform reisel prices on advertised articles, when the manufacturer thereof is subject to full and free competition. We believe this would be to the best interest of the public, the retail desier, and the manufacturer. Our position agrees with that taken by Mr. L. S. Benades in an address delivered in New York May 14th at a dinner given by the Association of National Advertising Managers.

It is summarized in the May magnetin issue of the Outlook.

Unition.

To illustrate: We have manufactured for half a contury or more an instituteneous chocolate of unusual merit. This is sold to retail grocers at 62½ cents a pound, and the advertised retail price is 75 cents a ound, showing for the retailer a profit on his selling a

price of about 17 per cent. The majority of dealers do not sell this article, chiefly because the leading grocers for many years have sold it at "out prices" ranging from 65 cents to 70 cents a pound. The stores that out the advertised retail price are willing to sell that out the advortised retail price are willing to sell instantaneous checolate at a price that nets them a loss, when their cost of doing business is considered, making of course more than the average profit on articles that are not advertised and on which there is no standard price. The results of this condition are to prevent the wide distribution of this specialty, as the average dealer does not care to carry in stock an article that allows him less than a hving profit, making it unprofitable for us to advertise it. This price cutting finally results in a failure to serve the large numbers of people who would be glad to purchase the chocolate at the fair competitive price of 75 cents a pound at the nearest grocery store. Please bear in mind that this price is fair, based upon the cost of producing the article, and is in direct and full competition with every other chocolate on the market—It happens to be the highest priced of all, but there is absolutely no reason for anyone paying the price except the unusual quality of the product. We believe th

of the product.

We believe that when we sell this article by means
of our own publicity campaign we should have the
legal right to fix the retail price, and that the law should
protect us, and the public and the average dealer against
the price outter.

t we expressly do not believe that any retail price should be protected that is not regulated by full and free competition. That is, we do not believe that manufacturers or trusts should be permitted to fix high prices by eliminating competition, nor should they be permitted by temporarily cutting prices to destroy the business of smaller competitors, their usual method of securing a monopoly.

STEPHEN F. WHITMAN & SON, INC.

Philadelphia, Pa. J. W. WHEELOCK, Adv. Mgr.

## The Birth-months of Genius

To the Editor of the SCIENTIFIC AMERICAN:

The influence of season upon the human embryo, in so far as concerns the mental and moral traits of the after-born individual, appears to have received scant attention at the hands of science. Its influence upon the physical organism seems not to have challenged the physical organism seems not to have challenged over-much investigation. As a possible factor in sex-determination the subject has been considered, and the conclusion reached by Dusing and others that more males are born in the human family during the cold months of the year. That temperature, however, and seasonal changes may have many indirect and as yet unsuspected bearings upon embryonic life appears to be recognized by scientific writers. As affording a basis for a future study of the influence of season, during the sensitive stages of the pre-natal

As anorems a coast for a truther study of the intrense of season, during the sensitive stages of the pre-natal life, not only upon the physical but upon the mental and moral being of the individual in after life, the present writer has tabulated the birth-months of the world's thousand most famous men and women, using for the purpose the list of names published by Prof. J. McKeen Cattell in the Popular Science Monthly for Pebruary, 1903. Of the thousand names, the information desired was afforded as to 431 by the authorities soun cesures was amorded as to 431 by the authorities at the writer's command, and of these 45 were born in January, 40 in February, 34 in March, 36 in April, 38 in May, 20 in Jule, 29 in July, 34 in August, 36 in September, 36 in October, 41 in November, and 36 in December

A tabulation by vocations of the names in our lists yields some curious results. Of the eminent perso connected with the church, for example, we find find that 27 were born in the latter half as against 8 in the half of the year, and much the same is true of poets, with whom the ratio is 25 to 15, and scientists, with whom the proportion is 30 to 24. On the other hand, 25 philosophers saw the light in the earlier half as against 15 in the latter half of the year, and in the case of states-men the numbers are 25 to 20, in the case of military oters 22 to 13, in the case of musical composers 8 to 4, painters and sculptors 8 to 6, and in the case of writers, including historians but not including those classed in the biographical dictionaries as philo ophers, 26 to 25

unlikely, these figures are morely accid and without special significance. It is noteworthy, however, that the calendar of birth-months for men of genius, formulated thus from the writer's data, of genius, formulated thus from the writer's data, appears to answer closely to that for the ordinary population, for, according to Mulhall's "Dectonary population, for, according to Mulhall's "Dectonary population, for Europe are: January 107, February 107, March 107, April 103, May 99, June 94, July 93, August 95, September 101, October 99, November 97, December 98. Allies in our table and that of Mulhall, be it remarked, a sheelded diminution in number of birth appears for June and July, and in both the earlier months of the year show a larger average than the closing months.

## The Electric Production of Steel

## From the Early Experiments of Siemens to the Thirty-ton Furnace of To-day

IT is of course impossible, within the limits of the present article, to attempt an elaborate and detailed survey of the progress of the art of applying electric energy in the production of from and steel. Our purpose is rather to give a lirel frisand, commencing with the classic work of Steneus in the late seventice, and touching upon the more important steps by which the art has been brought up to its present degree of enforcement.

The importance of this latest development in the metallury of from and steel is little understood by the general public, who may be surprised to learn that the scleric furnace has been brought to a state of such efficiency that it is now possible to turn out a steel equal in quality to the costly eracible steel, how any another to many of the leavy tracks which hitherto have been restricted to the use of Bessener and open-harrin steel. The readers of the Surstruck American will apprehent the spirituance of the above fact, when we stare that steel raths are being made in commercial quantities from the high-grade steel which it is now possible to produce in the electric furnace, and that these raths, because of their purity, hardness and ductility, have shown in active service that they are well able to stand up under the heavier wheel loads and higher speeds of modern railway traffic, even under the severest conditions of whiter temporature.

Mainly because the steel rail enters so largely into the question of safe railroad travel, we have mentioned this nuterial as one of the heavier products that will benefit by the excellent qualities obtainable by electric rediaing. It must not be supposed, however, that the field of application of electric refining is limited to this, or to a few specialities. We have before us the statistics of the Heroint electric furnaces now un operation and building, and the kind of materials they produce; and from this we find that, among other products, they are turning out steel for the construction of war material such as guns, protective shields, projectives, etc., and for locomotive tires and axies, seamless tubes, dynamo sheets, wire and wire rods, tool steel, little grade castings, and other products calling for steel of high quality.

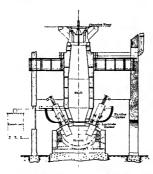

Until the appearance of the electric furnace, the process of making the luik of the commercial steel for ralis, beams, griders, plates, rods, etc., consisted in the sancting of the fron ore in the blast furnace, by charging the furnace with iron ore, coke and lime-stme, and reducing the ore by the facre combustion of the charge under the action of a powerful not blast. The multen tron was then rid of its inspurities either in the Beesemer converter or in the open-hearth furnace, in the course of which treatment the steel was brought up to the proper composition by the further elimination of current and the regulation of the desired amount of curbon and other destrable constituents. Great as were the improvements effected by the litroduction of the Bessemer converter and the open-hearth furnace, both as to the quantity and quality of the product, the further purification of the steel and the securing of the high-class material of the cruchble process, without an

undue increase in the cost, has been the goal at which the steel makers have aimed for many a decade past. It is largely because the electric process remders if possible to make steel in large quantities possessing the high qualifies of crucible steel, that electric rething has proved such a valuable contribution to the metatings of steel.

SIR WILLIAM SIEMENS,-For the gen esis of the electric retining furnace, we must go back some three decades and speak of the classic experiments of that who foresaw the great possibilities of the electric furnace for steel manufac-He built two furnaces, one of which was a crucible of graphite some other refractory material, which was inclosed in an insulating jacket. One electrode was held in the bottom of the crucible and another passed through the cover and was provided with a d vice for maintaining it at the proper distance from the lower electrode. metal was placed in the furuace and covthe lower electrode, and the arc was formed between this charge and the upper electrode, in his other furnace the two electrodes were placed horizon-tally and opposite one another, the arc

melting the charge beneath it by radiation. As we shall see inter, these two furmaces anticipated two of the modern, well-known, electric sieel furnaces. Like many a famous inventor, Stemens was ahead of the state of the art; it is the modern development of electrical engineering that has made it possible to upply bls system

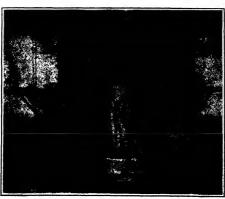

o the reduction of steel to commercial quantities
THE ELECTRIC SMELTING FURNACE—When the devel-

Latest type of Swedish electric smelting furnace.

Section through Stassano furnace.

Stassano electric arc furnace at Turin, Italy.

opment of electrical audinesting had advanced to the point which warrant, on secured to warrant, its application to steel making on a commercial scale, it was inevitable that the entry efforts would be directed the substitution of electrical energy for the fuel and hot bination fine smelting furnance; and the efforts of entry of the smelting furnance; and the efforts of entry of a microscapil electric smelter. Of this type was the interaction of a microscapil electric smelter. Of this type was the interaction of the shown in the stansaction prompting illustrations. This is a rotating furnance, which consists of a cylindrical steel casing, fund internally with first-trick, and rotates shout an intellined axis upon a set of rollers. The charge consists of ron or pulverised and made up, with charcosi and other necessary elements for reduction, into briquettes. The current is passed through the lower channel by contact rings, and projecting into the turnace are everal electricodes whose position is regulated by menus of cylinders, one of which is shown in section. As the gasses are formed, they are led off through the invalidation of this kind which is now at work in the sovernment shops at Turin, for the melting of steel series.

That there will be my world-wide substitution of the electric reduction furnace for the present blast few, mace is unlikely. The change can be made profitably only in those localities where coal is dear and the production of electric energy is cheap. As matters now stand, if the electricity has to be generated through the medium of coal-fired hollers, stems engines and dynanos, the electric smaller cannot possibly compete with the blast framce: but it has been proved, notably in Sveden and also in California, where foel is relatively dear mid the supply of electricity generated in hydroelectric works is abundant and cheap, that excellent high from may be produced successfully on a commercial

The Noble Electric Sieel Company of California, where charcoul is obtained at low cost, are using successfully an oblong furnace with four electrodes projecting downwardly from the roof of the furnace. The Swedish reducing furnace follows in construction the general lines of the blast furnace, the charge being introduced at the top and the hot metal being tapped off at the bottom. The place of the heart in of the blast furnace is taken by a domed receptacle built at the bottom of the furnace, through the roof of which from two to six electrodes project diagonally into the furnace. That the Swedish works are producing pig iron on a commercial scale is shown by the fact that last year the total unique was might some commercial scale in shown by the fact that last year the total unique was a long to the same commercial scale in the same commercial scale in shown by the fact that last year the total unique was a long to the same commercial scale in the same comme

year the total output was about 20,000 tons. ELECTRIC REPRIME PURMENS.—The field of electricity in the manufacture of steel will be confused mainly, for the present at least, to the refulluy of steel. For this work the various furnaces may be divided under three types: First, tinese in which the heat is produced by the relestance of the metal in the bath, a type which has never passed the experimental stage; second, those in which the heat is due to electric curront induced in the bath; and, thirdly, those in which the metal is heated by an electric are cylicher by direct contact of

the arc with the metal or by radiation from a super-imposed arc). Of the three types, the electric-arc furnace is the most successful, and it is in such extensive use us to warrant the belief that an tiensi for the refining of steel it may ultimately have exclusive command of the field. The induction furnace, which was formerly a promising rival, has done good work and is still in use in some of the more important works, particularly in Germany. The resistance furnace has gone very little beyond the experimental stage in the refining of steep fining and the still in the stage of the stage of the refining of steep stage in the refining of steep stage.

The Gin Hesistrance Funnace.—The Gin furnace, as shown in our illustration, consists of a car, upon which is constrarted in furnace of masonry, provided with a iong serpentine channel 4, connected with electric pole pieces at B. This channel is filled with the metal to be treated through hoppers H. The desired temperature for treatment is obtained by varying the current passing into the hot metal in the beth.

THE KJELIN INDUCTION FURNACE.—
The induction furnace, of which the Kjellin, shown in the accompanying illustration, is a well known example, is practically a large crucible free from electrodes in which the steel is heated by

The Gin resistance furnace, an early experimental type.

Sections through Gin furnace.

Kiellin induction furnace.

an induced current. The charge is protected from the action of any farnace gases and from oxidation. This farnace consists of an annular hearth A formed in the masonry body of the furnace; an fron core C, one arm of which passes through a central hole formed within the annular hearth, this arm being surrounded by a primary coil D. The charge in the annular hearth A is maintained at the desired temperature by varying the current through the primary coil D. The torace is closed by removable cover plates, not

shown in our drawing.

The Richtaine-Romentaines Industrian Firmace.

The Right furnace above described is necessarily of limited capacity, and both its diameter and cross section must be increased if there is to be an increase of the charge. If the cross section is increased, the electrical resistance would not be sufficient to obtain the necessary working temperature. If the diameter is necessary working temperature. If the diameter is necessary working temperature if the diameter is uncreased, the distance between the primary and secondary windings and the magnet cell in proportion and the losses due to dispersion would be increased. These difficulties were sought to be overcome in Germany by Richillug and Rodenhauser, and in Norway by Horth.

The Richilang and Rodenhauer furnace, like the

The Röchling and Rodenhauser furnace, like the Kjellin, is of the induction type, but with a single primary winding A around each iron core. The bath is in the form of a figure 8, with that portion of it D bying between the two cores of much greater width than that fying outside of it. The secondaries are two; one being its motion metal, and the other a copper winding B, which is connected with metal plates E in the furnace walls. The current passes from B through E and a mass G of highly refractory electric conductors, to the metal D in the bath. The metal is thus subjected to heating effects both by direct induction and by the current passing through the bath, between the opposite sate N describes the subjective N is a subjective to the proposities and N is described to the subjective N in the subjective N in the subjective N is a subjective N in the subjective N in the subjective N is a subjective N in the subjective N in the subjective N is a subjective N in the subjective N in the subjective N is a subjective N in the subjective N in the subjective N in the subjective N is a subjective N in the subjective N in the subjective N is a subjective N in the subjective N in the subjective N is a subjective N in the subjective N in the subjective N in the subjective N is a subjective N in the subjective N in the subjective N is a subjective N in the subjective N in the subjective N is a subjective N in the subjective N in the subjective N is a subjective N in the subj

THE HEROULT ELECTRIC ARE FURNACE—We have no recently (SCHETURE AREAGEAN, June 7th, 1913) described the 15-on Heroult furnace as installed by the United States Steel Corporation at their works at South Chicago and at Worcenter, Mass., that a brief reference will estime in the present article. The Heroult furnace will estime in the present article. The Heroult furnace of the present article is an open-heart feetpale. It is no empresed as to have a titlen motion from the chapter of the posting side. The necessary

121/15 be 2011

imperature is secured by the flerce heat of an electric are formed between electrodes and the metal buth. The electrodes pass through the roof of the furnace and are maintained at the required distance above the hot metal by automatic, electrically-controlled devices.

The phosphorus is removed in the basic electric furince in much the same numer as it now is in the basic open-hearth furnace—by the use of time and oxide of iron. The resulting sing containing the phosphoras is tapped off, and a new entainting the phosphoras is tapped off, and a new sing of burned line and finor spar is formed. When the sing is motive, coke dust is added, and the resultinut carbide of calcium is produced. The free carbon, and, possibly, the carbide of calcium in the sing, with the aid of the carbon and manganese in the bath, eliminate the deleterious oxygen from the steet.

The advantage of this process of reliating is, that the resulting steel is free from segregation, is almost perfect in structure, and shows no exide or sing inclosures under the microscope. A similar furnace is in successful operation at Worrester, Mass.

That the electric furnice of large size is equable of turning out large quantities of steel, such for instance as are required for rall manufacture, is shown by the results obtained by the United States Steel Corporation, who, by the way, have expended in Horie experimental work, to date, over \$800,000. They have already produced about 1,0000 tuns of electrically-reflect steel rall, and most of it has been in service for the past three and one half years. During that time there has not been a single case of breakage, the steel, in addition to its purity, showing a remarkable toughture.

The great strides which have been much in electrical reduling during the post for revers me shows the reduling during the post for revers me shows the reduling during the post for revers me shows the reduling the post for reducing the post fo

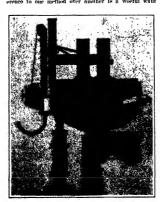

## The Measurement of Lights of Different Colors

PROF. HERRERT E. IVEN in two learned technical articles which have appeared in the Philosophical Magazine gives the result of an investigation into the photometric effects of lights of different colors. His results are interesting enough to present in a popular account.

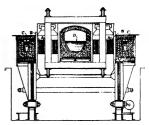

account. The advent of incandescent lamps of great efficiency and other new lights with a wide range of color, the prospect of an even larger variety in the near future which will diverge in that still further from present lluminants, all render the problem of measuring the imminosity of various hues, one of great importance. The mare comparison of two differently colored lights, is no more possible than its the exact comparison of sound with odor. Some nesholes, of course, have been discovered which in the process of measurement evade or eliminate the difference in hue. But different methods require different shandards and Dr. Ives promised to the process of the same methods require different shandards and Dr. Ives pro-

poses to obtain a relation between the various criteria.

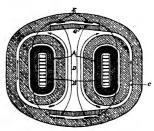

The chief obstacle, he says, in the way of giving preference to one method over another is a weeful want

The Heroult 15-ten are furnace at South Chicago,

Cross-section through Röchling-Rodenhauser

Horizontal section through Röchling-Rodenhauser induction furnace.

of statistics or data. These defects Dr Herbert Ives proposes to remedy. Of the methods of light measurement which have been applied to differently colored lights, one is the method of equality of brightness. Two colored lights limitation two portions of a background or photometric—measure of light—screen. The relative intensities of Hiumination from the two lights archanged until the two differently colored fields give n sensation of equal brightness. The illuminations are then said to be equal

The method of aculty of sight is merely the way of proving two colors squal when the same fineness of detail is just distinguishable by each, while the method of critical frequency holds that two illuminations are equial when the flicker produced by rapid alteration of one illumination with black disappears at the same speed of alteration as the other

speed of atternation as the other. Two illuminants are also said to be equal when upon rapidly alternating one with the other no sensation of flicker results. The speed of alternation is such that the slightest change of either will cause a flicker.

Dr Ives discovered that the lest standard must center uround the filcker and the equulity of brightness of the colors. So he then determined by the two methods the degrees of luminosity of the various tints and colors of the spectrum. The original findings of his numerous experiments are most helpful.

He found that the fifteer method is much more sensitive than the equality of brightness method, particularly where colored lights are concerned. The result with the fifteer method is more soully represented than with the equality of brightness plan. White decrease of illumination shifts the maximum of luminosity toward the blue in the equality of brightness method, yet with the fifteer method it whits toward the red

was the ficker method it shifts toward the red Decrease in the site of the measured field of light in low illuminations, shifts the maximum of luminosity toward the red for the equality of brightness—called the yellow spot effect—and toward the blue with the flicker method. The results are also most different at low degrees of illuminations upon large fields. They are merrest together at high illuminations and a small surface or field of light.

With the hope of shedding some light on the peculiarities of the flicker method, other experiments were carried out. Dr. Ives' results has served to clear up the seeming discrepancies of various observers, and these were brought into accord by proving that a change in experimental conditions yields changes in the results.

He also shows that the retina is found to be more sensitive to flicker furthest away from its central point, only on momentary observation before fatigue or adaptation sets in. The point of heat vision—the foves—is more sensitive to red flicker, the periphers or outside part of the relina, is more sensitive to blue lights. These differences are greatest at two degrees of limination.

## The Heavens in August

## The Summer Constellations: Jupiter's Satellites

By Henry Norris Russell, Ph.D.

S o far as predictable events are concerned, there will be little to attract the attention of the American ateur in astronomy during the coming month There is, to be sure, a partial eclipse of the Sun on August Blst, but the Moon is then so far north of the plans of the Earth's orbit that the central line of her shadow es the Earth by about 1,500 miles, and only the hern edge of the peuumbra (the region of partia shadow, from which only a fraction of the Sun's light ded) sweeps across the northern portion of our The region from which the eclipse is visible is therefore unusually small, including only Greenland, leeland, Labrador, Newfoundland, and the adjacent seas, with the extreme northern portions of Nove

The Sun, as seen from all these regions, will be low in the west at the time of celipse, and little more than one teuth of his diameter will be obscured. Nevertheless, granting clear weather, the eclipse should be dis-tinctly observable in Newfoundland, beginning a little after 5 P M. by Atlantic time (which is kept by the

rallways there), and lasting about half an honr. On the southern shores of the Gulf of St. Lawrence the ecity be nimost vanishingly small, but the very shallow notch in the Sun's northern limb may be observed with a field-glass (promay be observed with a held-glass (pro-tecting the eyes by smoked glasses) at about 5:25 P. M by Atlantic time (or 4:25 by Eastern Standard time). Unless the reader's holiday may insp-

pen to take him thus far afield, he will and to the planets Juniter and Uranus. but there is no lack of laterest here

Our map shows what stars are to be seen in the evening skies, and just where to look for them at the hour given below At an earlier hour all the stars (except those in the north below the pole will be farther to the east; i e., they will be higher up if in the western sky, lower down if in the east, and more to

the left if in the south, and so on.

The student whose wish is to be familiar with the summer constellations may begin by looking straight overhead Here he will see the Milky Way stretching from northeast to southwest right across the sky, and in it a large and conspicuous cross of stars of which the brightest is at the head of the figure. This is the constellation Cygnus—the Swan. It takes very little imagination to see the actual figure of a bird in this group of stars, the brightest star making its head, the arms of the cross extended farther by other stars, its wings, and the foot of the cross its tail. With this as a starting

point we may proceed in any direction. The line of the Swan's wings, extended toward the northwest, points to two bright stars, not far apart, which form the eyes of the Dragott. (β and γ in Drago on the map.) Much lower down, lu the same line, we come to the haudie of the Great Dipper; or, if we pref the tall of the Great Boar

if now we hold our map so that the Dipper is at the bottom, we can pick out at once every bright star in this part of the sky, find to what constellation it In this part of the sky, find to what constellation it belongs, and what Greek letter has been assigned to it, and trace the outlines of the constellation. In the same way we may proceed in any other direction from our starting point, finding lu the west the two very bright stars Vega (high up) and Arcturus (low de in the southwest the constellations Scornic, now very low, and Sagittarius; in the south, higher up. Altair and the other stars of the Eagle, and below it the fainter pair which mark the head of Capricornus; in the southeast the isolated bright star Fomalhant; iu the ens; the Great Square of Pegasus standing on one corner; and in the northeast Cassdopela and Perseus, both in the Milk) Way, and the latter just rising. less conspicuous constellations may now be identified with the uld of the map.

The observer who has a field-glass at his co will find interesting objects in the stars i in Uran Major, and a and \$ in Capricornus, all of double. The first two can be easily separated by the maked eye, but the faired whose companion is much failner, requires option aid. About half-way between a and 8 in Cygnus is another pretty pair, and a second

is close to the bright star Vega. The Great Nebula in Andromeda (shown on the map) is also easy to find, and there are fine star-clusters in the Milky Way be-tween Cassiopeia and Perseus, and in Sagittarius.

st interesting of all is the great planet Jupiter, which, though low in the southern sky, among the stars which, though low in the southern sky, among the stars of Sagittarias, outainse all else. This great brightness makes Jupiter a very striking object, even in a field-gias. It takes a powerful binocular, good focusing, a steady hand, and a trained eya, to see the plane? disk distinctly: but the assidities, especially the two outer of the four, are not hard to see. The beginner need not be alarmed, however, if on the fart night need not be marmad, nowever, it on the mrst ingot when he observes Jupiter, he can see no moons near it, or perhaps only one; for if the satellites are nearly in front of the planet or behind it, it takes a more powerful instrument to reveal them. A little patience, however, in watching the planet on successive nights will be rewarded. The third satellite, which is the brightest of all, can be seen on the east of the planet on August 1st, 8th, 15th, etc., and on the west

NIGHT SKY: AUGUST AND SEPTEMBER.

5th, 12th, 19th, etc., its period of revolution being 7 days 4 hours. The fourth, which is fainter, but goes almost twice as far from the planet, may be seen on the east side on the 2d and 19th, and on the west side on the 11th and 27th, and for some three days on either

The other two estellites are so much nearer the planet that they are not as easy to see with a small glass; and their periods are so much shorter that it is harder to keep track of them. The second satellite which completes a revolution in 8 days 13 hours 18 mlp course, west of the planet at the m

With this luformation, the observer may out which satellites were observable at any given time.
All calculation can be avoided by recourse to the Nautical Almanac, which gives diagrams showing exactly

where to look for all four satellites every night.

The fortunate possessor of a telescope three inch or more in aperture may find still greater interest in the study of Jupiter and his system. With such instrument, the vital forms of the planet's disk and the belts which cross his surface parallel to the equator are easily seen, and with a little care, it is possible to which the passage of markings across the surface, as they are carried round by the planet's rapid rotation. The celipses and transits of the satellites are fascinat-

ing, too. The approach of a satellite to the edge of Jupiter, and its disappearance into or reappearance from, the planet's shadow, can be watched with a small instrument. It takes a larger telescope to see the shadows of the satellites, as tiny black dots crossing the planet's disk, and a still more powerful one to see anything of the satellites themselves when in front of the planet. During the present month, the phenomena observable in the evening in the eastern part of the United States are as follows

SATELLITE I.

Is in front of Jupiter on:

August 7th, from 6:51 to 9:00.

August 14th, from 8:39 to 10:57. August 18th, from 10:27 to 12:45.
August 28rd, from 4:54 to 7:12.
August 28rd, from 6:44 to 7:12.
August 20th, from 6:44 to 9:02.
Is behind him, or in his shadow, on:

, or in life shadow, on:
August 6th, from 9:47 to 12:46,
August 18th, from 11:30 to 2:39,
August 18th, from 5:57 to 9:08,
August 22nd, from 7:45 to 11:68,
August 29th, from 9:35 to 12:58,
August 81st, from 4:02 to 7:20, NATELLITE II.

Is in front of Jupiter on:

August 4th, from 7:25 to 10:15.

August 11th, from 0:44 to 12:34.

August 18th, from 12:05 to 2:55. Is behind him, or in his shadow, on August 13th, from 3:54 to August 20th, from 6:17 to 11:07. ist 27th, from 8:42 to 1:45.

Satellite III. comes out of eclipse at 11 520 on the 7th, goes behind the planet at 8:35 on the 14th, comes out again at 11:51, and disuppears into the shadow (which, as seen from the Earth, lies on one side of Jupiter) at 12:17 the same night. It may also be observed to disap-pear behind the planet at 12:07 on the

Satellite IV. can be seen going into eclipse at 11:88 on the 15th, and going in front of the planet at 10:28 on the 23rd

All the times in the above table are given (as in the Nautical Almanac) Washington time, which is eight minutes slow on Eastern Standard time. It will be seen that the most interesting date of observation is the 14th, when two satel-lites are hidden at once, the first in front of Jupiter and the third behind him.

The planet Uranus is now also very well placed for observation, his position utes 44 seconds of right ascension and while that on the 80th is 20 hours 27 min-

utes 29 s provided with detailed star maps may caslly flud him provided with detailed star maps map (saily mud him with the sid of three small stars in Capricornus, which may be found by drawing a line from a through  $\beta$  Capricorni, and prolonging it to the southward not quite twice the distance between them. These three stars, c, wand a Capricorni, form a nearly equilateral Due east of them, at about the same distance as that between a and  $\beta$  Capricorni, is another faint star, v Capricorni.

so stars are between magnitudes 5 and 51/2 s of the 6th magnitude—a little fainter—and Uranus is of the 6th magnitude—a little fainter—and lies about 1 degree south of the line joining v Capri-corni to the triangle. The lower side of the triangle points almost straight at him. At the beginning of the month he is about twice as far from the ringing so the month he is about twice as far from the triangle as from w, but at its end he is nearer the former. He can only be seen with the naked eye on a very clear dark night, but is conspicuous in a field-glass. The neighborhood of these good reference stars makes this an unusually good time to hunt for the planet.

Of the other planets, Mercury is in conjunction with

the Sun on the 3rd, and cannot be seen until the latter the Sun on the 3rd, and cannot be seen until the latter part of the month, when he appears as a morning star, in Cancer, rising before 4 A. M. He tig at his greatest apparent distance from the Sun, 18 degrees 28 minutes, on the 22cd, and should be easily visible.

on the Mand, and should be easily visible.

Venus is morning star in Gentlar, rising about 2 A. M. and acceedingly bright. Mare is likewise a morning star, in Taurus, rising about midnight, and appearing a little brighter than Aldebaran. Saturn is close by; (Concluded on page 89.)

Cody and His Proposed Transatlantic Flight

IN an endeavor to capture the London Daily Mail's prize of \$50,000 for the first aviator to cross the Atlantic within 72 hours, Col. F. S. Cody, the well-known Anglo-American airman, is building a shydroaeroplane in which he bopes to cross the ocean in 20 hours. In order to do this he will have to average at

ch lies between England and Newfoundland.

It is believed by those who have made a study of he question that the first flight will be made without a the que stop, as the high waves of mid-ocean would prove dis astrous to flying machines of the present day. The problem of deciding from which side of the water to start is also occupying the attention of those airmen who intend to compete for the prise. Starting from England, a fiver would travel with the sun and wou have daylight for about 22 hours, while a start fro Newfoundiand would give him only 14 hours of light. However, he would have the advantage of the prevniling western winds in mid-ocean.

## Richard Börnstein

THE death of Prof. Richard Börnstein on May 18th removed a conspicuous figure from the circle of German meteorologists. Although he was professor of physics at the agricultural high school of Wilmersdorf (a suburb of Berlin) he had for years devoted his at-(a signific of berinn) he had for years devoted his at-tention almost wholly to meteorology, especially the practical side of the subject. To his efforts chiefly was due the organization in Germany a few years ago of a system of weather-forecasting and map-publishing stations analogous to those of the United States Weather Bureau. Among his voluminous writings was an admirable elementary textbook of meteorology, a new edition of which had just appeared at the time of his death. For many years Börnstein was editor of the first two of the three annual volumes of the "Fortschritte der Physik"—a publication that is indispenable to every worker in the physical aciences. He was
a member of the recently organized International Commission on Agricultural Meteorology.

## Armature-winding Machine

RESIDENT of St. Louis, who for years has been A engaged in the electrical repair business, has re-cently built a machine for rewinding small armatures. device takes either diametrical or chord windings in either straight, twisted, open or overhung slots, and it may be adjusted to the armature in two or three minutes. It consists essentially of a universal two-jaw chuck which holds the armature while it is being would. The jaws are shaped to guide the wire into the slot. Between the jaws are two scrow stope which are adjusted to fix the point at which the jaw arrip the armsture coil, so that when the slot on one side is set and the core is held against the slot, the other slot will line up with the opposite jaw. The jaws are tightessed upon the arpasture by means of wrench wheels of such preportions that the operator cannot readily scret to much pressure on the delicate core and damage the teeth. The machine is operation may be slipped on the shaft of a small perior, say 1/6 lorset property is 500 to 460 revolutions per simute, and prefreight is should be provided with a fort controller mich as used on sewing tachnic motors. The device may also be introduced with a fort controller mich as used on sewing tachnic motors. The device may also be introduced with a fort controller mich as used on sewing tachnic motors. The device may also be introduced with a fort controller mich as used on sewing tachnic state made over the control of the terms of winning the magnitude with some fill the terms of winnings, the instead of the terms of winnings, the factor is proposed with the edges of the The jaws are shaped to guide the wire into

is we overhanding the teeth of the slots a trifle. The jawa overhanding the teeth of the slots a trife. The device is then turned and the wire is automatically fed into the proper siot. When the first coil is fishished, the wranch wheels are loosening, and the core is turned to the next slot; when the next evid is wound, and so on, until the suttree winding is completed. For arms-tures with twisted slots the jawa may be adjusted to the proper audie. With a device of this kind resist on small armatures, which formerly had to be done by hand, is now greatly expedited.

## The Tin-plate and Terne-plate Industry

TATISTICS for the fin-plate and terus-plate indus-STATISTICS for the implace and remember of try in the United States for 1909 are presented in detail in a bulletin soon to be issued by Director Harris of the Bureau of the Census, Department of Commerce. d under the supervision of William M. It was prepare Stenart, chief statistician for manufactures

Tin-plates are thin plates or sheets of steel or tron.

Automatic armsture-winding machine

known as black plates, coated by dipping in a bath of molten the.
Terne-plates are black plates control, in like manner, with an alloy of tin and lead known as terne mixture. the proportion of tin varying from 10 to 35 per cent. The term "terne is taken from the French, and means dull or tarnished. On account of the lead in the mixture terne-plates are much dulter in appearance than tlu-plates, sometimes known as bright plates.

Ttn-plate manufacture involves two radically different pro the rolling of the black elates and the dipping of them in the or terms mixture The manufacture of black plate ts a rolling-mill operation, and the bulk of the dipping is performed by the dipping departments of such rolling intils.

Of the 34 autabltshments to the combined industry in the United States in 1900, 27 both rolled black

plates and dipped them, three rolled black plates but had no dipping departments, while four were engaged in tin and terms dtoping only. The number of each of these groups of establishments was smaller in 1900 than in 1800; but the decrease was greatest in the number doing a dipping business only, and the num-ber making black plates will no dipping departments. There has been a growing lendency to consolidate the two branches of the business

The net value of all products of the black-plate mill and dipping establishments in 1900 was \$65,378,580, of which amount the value of the and terms plates represouted 70.1 per cent. In 1904 the value of the ttn and terme-plate product formed 800 per cent of the net value of all products of these establishments, and in 1809, 75.7 per cent. The value of products of the ludustry was 58,2 per cent greater than in 1890. value added by manufacture—that is, value of products less cost of materials—was \$22,948,150 in 1909, and the number of wage carners, 18,956.

## Higher Electric Lamp Efficiency

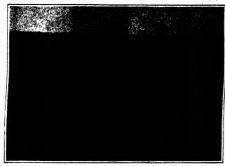

N EW incondescent lamps which contain especially shaped tungsten filaments and are filled with nitrogen at a pressure of about an atmosphere, will soon be obtainable. The types which it is expected to develop first are adapted to comparatively high current consumption, six amperes and above, and operate at an effi-cioney of half a watt per candle-power. This is fully twice as high an efficiency as the most efficient incan descent lamps heretofore available. The new lamp The new lamps promise to be of particular value in a field not heretopromise to be or particular value in a neu not hereto-fore covered by incandescent lamps, and should greatly broaden the applications in which they can be used advantageously, particularly in the direction of very large candle-power units

## The Cost of Orchard Heating

THIS is the subject of some elaborate statistics by thilly answering the question "Does frost fighting pay in I'tah?" Assuming 30 degrees as the temperature w which heating is necessary, he finds that for the first degree-i e, to heat from 20 to 30 degrees the cost is 60 cents per nore per hour, while further fall of temperature the cost increases 40 cents per degree per acre per hour. Thus to heat the orchard to the sufety mark with a temperature of 20 degrees the cost is \$4.20 per acre per hour. It is also assumed that if the temperature falls below 20 degrees, the crop cannot be saved; and this may happen after a large amount of fuel has been expended. Again, the business of firtug presents many chances for small leaks of one mother, and much nunccessary firing to apt to ne in the attempt to err, if at ull, on the safe side. Finally, there is the question whether the scot-laden and smoke-covered pollen can continue its work of fertilization. Some of the growers who in the just have fully" fired their orchards have now abandoned the practice. On the whole, Mr. Alter's deductions are couraging, so far as his observations in Utah extend. hnt of course do not, necessarily, apply to other parts of the country, where frosts are less frequent and of the country, where frosts are less frequent severe, or where fuel and labor are less expensive.

Earthquakes and Rainfall .-- It has been cor that excessive atmospheric precipitation might favor the occurrence of earthquakes by increasing the supply of subterranean water, leading to a washing away and col-lapse of portions of the earth's crust Count de Montessus de Ballore has published in the Comptes Rends results of a painstal results of a painstaking comparison between 4,136 earth-quakes and the rainfall conditions preceding them. He concludes that there is no relation of cause and effect

## Curious Exotic Fishes By Jacques Boyer

The breeding and keeping of small excite Biles of strange forms, strikling colors and curlous habits has been greatly promoted in Germany, in recent years, by the efforts of enterprising Hambarg importers. At present several French placefultratts are endeavoring to make this custom, of Chinese and Japanese origiu, popular in France.

gin, popular in France.

The aquaritums of M. Lefèvre, in particular, are filled with rare and superb specimens, brought from China, Japan, Africa and South America, some of which we have succeeded, though not without difficulty, in photographing in characteristic attitudes.

Let us first examine the telescope fish, which Carbonnier tried to acclimate in France forty years ago. This monstrous variety of carp, a creation of the Chinese and Japanese fish breeders, who are past masters in the art of deforming nature, has an almost globular glistening body gilded on the sides, double dorsal fins and a long tail of peculiar shape. Its eyes and their sockets are very prominent and re-semble the object glasses of telescopes, whence the name telescope fish A carp possessing titls abnormal feature was discovered in Japan in the sixteenth century, since which epoch the peculiar churacter has been perpetuated and combined with many variations in form and coloring, by cureful selection and crossing. By these means, combined with ingenious processes and devices which it would be tedious to describe in detail, the Japanese breeder have succeeded in preserving various individual peculiarities. In order to increase the protuberance of the eyes, for example, the fishes are kept in an aquarlum which is dimly lliuminated by light coming from a single point. The eyes of the young fry are normally formed.

A Japanese telescope fish, the "fan tail."

Bengalese catâsh (Sacobranchus singio).

The variety known as Yea-tan-yen or "well tail" preserves the normal structure of the eye during life, but its delicate, transparent tail attains an enormous size and fails in graceful folds, like a veil, producing effects that a "serpentine" dancer might envy, when the little fish moves in the sunlight.

Other Japanese varieties of the telescope fish are the "sheep's nose," which owes its mane to the convexity of its body; the "jag's snoul," which has a head resembling those of Asiatic swine, and the "fan tall," which raises and spreads its

tail in the manner of a fun-tail lyigeon. The Chinese breeders of telescope fish disdain these abnormalities of structure and devote their attention chiefly to coloring. By modifying the temperature of the water, and by impregnanting it with lime and iron, they produce startling shades and markings. Among the immunerable varieties thus obtained we may mention the "spotted," with a beily of silver, and sides and back marked with bine, yellow, black, rose and carmine dots; the crimson "ruby" and the "superh," with gift-edged scales, scarlet belly, and black or bright red markings on the back.

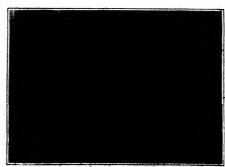

The globular form of all telescope fishes makes their equilibrium very unstable and their movement awkward. They are very subject to mainformation of the swim-bladder. Some individuals swim on one side, others on the back, because of displacement or atrophy of that organ. Some, called "tumbler higeons, others seement is the bottom of the water. In the case of hypertrophy of the swim-bladder, on the other hand, the fish remains at the bund, the fish remains at the surface.

Telescope fishes breed well in captivity, but as they devour their offspring they should be removed as soon as the eggs are laid. The young fry are fed, first with dried and pulverized silkworm pape,

## Dead Matter That Seems Alive

## Synthetic Ideas About Life

By Benjamin C. Gruenberg

rejected upon the nature of the elephant, after making a thorough investigation, to the effect that this animal is like a tree trunk, like a rope, and like a fan. This story was no doubt invested by some ancient oriental sage to show the failacy of generalizations based on fragmentary and unrelated experiences. When

chapter is an excellent one on mechanism versus mystictanguer is an excellent one on mechanism versus mysti-ctsm, in which we are reminded that scientific progress is made possible by escaping from magic words and for-mulæ into the path of trial and measurement. Of course the author rejects all forms of vitalism, and seeks to assimilate life processes to more familiar physical and chemical processes. Then he develops the idea of dyna-

mic centers, starting with Faraday's fields of force. Throughout the book there are excellent reproductions pholographs illustrating structures and movements obtained experimentally by diffusion in increasic solutions, in comparison with electrical and magnetic phenomena on the one hand, and with cellular phe-nomena on the other. The idea of dynamic centers in

Dr. Stephane Leer thirteen years ago, began his experiments with diffusion, he did

not claim to have physical basis of life; he was con-tent to point out merely the curious similarity between the diffugelatin and the cesses in fiving beings. Well trained in the metho modern science, he did not confuse the rone-like structure and the elephant: he said simply that the rope is like—nut an elephant, but like a certain part of an elephani. iarity with os-mosis and diffu-sion increased, he discovered more and more points of resemblance be nomens on the one hand and what happens in living organisms on the other. And gradually be has acquired the hal of thinking and speaking as exceptially of a rope, a couple of fans and three or four tree trunks

## The Airman and the Weather

Aeronautic Meteorology: A New Branch of Applied Science

By Charles Fitzhugh Talman

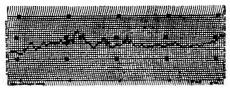

A ERONAUTICAL meteorology is to the A aeronaut what maritime meteorology and hydrography, together, are to the mariner. That it is destined to play an all-important part in the navigation of the nir is so obvious us to require no demonstration Taking this for granted, there are, however, certain questions to be answered in order to fix the status of this branch of knowledge in the aeronautical curriculum. How much, actually, do we know about the laws of the atmosphere bearing on aeronautics? Has the science reached a practical stage, or is it still so tentative and uncertain that, for the pres ent, the individual aeronaut should it upon his personal experience as a safer guide than the generalized knowledge now available? Is the meteorologist still, as formerly, learning more about the free stmosubere from the seronaut than the atter is learning from the meteorologist?
If for any reason the world became in-

terested in blowing soap bubbles we should not have long to wait for an exhaustive "Lehrbuch der Seifenblasenkunde" from 'Hernany It was in the normal order of events that a German gave us the first text book of aeronautical meteorology', and that we are promised from the san pen a companion work on aeronautical climatology; but it is sufe to say that few meteorologists were prepared to find in Dr. Linke's pioneor work a complete new branch of applied science, emiodying a wealth of information not only useful, but indispensable, to every person who risks indispensable, to every person who risks life and limb in navigating the air. This book fully answers the questions we raised a moment ago. Aeronautical meteorology has arrived.

The present writer has reviewed Linke's book in the SCIENTIFIC AMERICAN (June 24th, 1911, p. 630, and April 20th, 1912 n. 308), and it is not necessary to repeat bere what has already been said about its many merits. The young German author, though himself a practical aeronaut ns well as a meteorologist, is of course primarily a mere spokesman for the scientific aeronauts of his country, and his work reflects credit upon many besides himself. Our purpose now is simply to himself. Our purpose now is simply to cite a few facts from the work in question, and from other recent literature, serving to show to what extent meteorserving to show to what extent meteorology is already prepared to take up the new tasks imposed upon it by the sudden efforescence of the art of aeronautics.

It was a providential circumstance that

meteorologists had made a substantial seginning in the systematic study of the upper air a few years before the invention of the first practical scroplanes and diri-gible balloons. The new science of acrology—i. e., the survey of the atmosphere throughout its vertical extent, by all possible methods—dating, as a coherent body of knowledge, from about the beginning of the present century, pushes its investigasome three bundred miles above the The bulloonist, in extreme cases, earth. The bintoomst, in extreme cases, rhese 6½ miles; the aviator, 2½ miles. Thus it happens that much of the matter of aerology has no direct bearing on aeronantics. Even the remarkable isothormul lever, or stratosubere, the discovery of which, in the year 1902, marked an epoch in the history of science, lies at an altitude that it is doubtful whether any human being will ever travel whether any numan being will ever traver up to its lower boundary; though it is now almost daily entered by unmanned halloons carrying self-registering instru-ments. As to the lofty regions, beyond the reach of the sounding-balloon, in which the atmosphere is no longer "air." but hydrogen, or helium, or "geocorou'F Linke, Aeronauticoke Meteorologie, 2
tols, Frankfurt u. M., 1911.

Gustiness of the wind. Shown by the record of a Richard anomocine.

The speed of the wind at each moment is here registered in meters mograph.

"It is notorious that the greatest enemy of all kinds of air-navigation is the thunderstorm; . . . not only because of its electrical dangers, but because of the strong vertical air movements by which it is attended."—Linke tion is the th

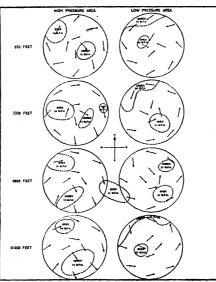

Fig. 3.-Variations of the force as d the direction of winds at different altitudes in high and low-pres

ium." or what-not, these are of no more practical concern to the serial navigator than to the procesic wayfarer on.

However, in order to reach the stratosphere every sounding-balloon must pass through the troposphere, and all ascents teorological kites are confined with in this lower stratum. Thus the great bulk of the data acquired by the aerologist pertains to regions accessible to the acro-

Before all things else the aeronaut is interested in the wind. The combined tical engineer have completely upact old-fashioned ideas concerning this element. No longer do we think of a wind as a steady horizontal stream of air, in which steady horizontal stream of air, in when every particle is moving at the same speed as every other particle. Such a wind would be a boon to the aeronaut if it existed, but it does not—as was first conciusively proved by Langley, and as is shown in the record of every aerological observation. In the first place, a wind is rarely horizontal, but has, instead, a more or less pronounced vertical com-ponent, of which the ordinary wind-vane and anemometer give not the slightest token. In the second place, no wind is absolutely steady or homogeneous; and most winds are quite the reverse. When two anemometers are place a few feet apart, one of them may, for a tirlef period, indicate a velocity twice as great as the other. Moreover, a single nemometer, if sufficiently delicate, will now incessant fluctuations in the strength of the wind. This "gustiness" is not well brought out in the records of the ordinary registering anemometer, but it is strikingly shown in those of the Dines pres-sure-tube anemometer, or the Richard anemocinemograph (Fig. 1), or the apparatus attached to the winch of a meteorological kite for recording the tension on

That the wind commonly has a vertical component, that gustluess is the rule rather than the exception, and that great variations in velocity occur from one place to another, are facts that the seronaut would soon find out for himself. It is the business of the meteorologist to tell him under what conditions he may expect these features to be most pronounced or most persistent, and what limiting mag nitudes they may assume.

For example, the meteorologist teacher the aeronaut to distinguish the typical forms of clouds, for the very practical purpose of enabling him to recognize those forms which are characteristic of vertical air movements, and those which denote mainly horizontal movements. A cumulus cloud is proof positive of the existence of a strong ascending current beneath it; while in the intervals between neighbor ring cumpil the air is likely to be sink-ing. Prof. Humphreys has happily de-scribed these vertical movements as "aerial fountains" and "aerial cataracts," and has shown that they are among the numerous causes of the so-called "hole in the air."

What maximum speed may be attained by vertical air currents? This is a question that the aeronaut would hardly care to have answered by a personal encounter with the extreme case of the phenomenon. The meteorologist, with the statistics of almost innumerable observations at his nmand, is able to tell him that ascendor some to test min that ascend-ing currents sometimes move at the rate of 25 or 30 feet a second, and that these rapid movements in the vertical occur-especially in connection with thundersalls. Furthermore, the met

## Inventions New and Interesting

Simple Patent Law: Patent Office News: Notes on Trademarks

## An Electrically Controlled Two-speed Rear Axis Design for Motor Cars

W FTR the constantly increasing cost of gasoline, status and status of the constant of the con

Now, however, there has been developed by a prominent Detroit automobile manufacturer a novel type of electrically controlled two-nieed, or two-gon, roar axie that bids fair to solve the eternal fuel problem in addition to having several other advantages of importance. The idea of the two-gear rear axie is not new, of course, for as long ago as 1907 the trillein Flat Commany filed application for patents on a device of the kind; and since then two other foreign and at least one ether American manufacturer have taken it up. The first American device appeared in Chicago at the automoble show early this year.

The method of controlling the goar changes in the new arie that has just been brought out, however, is herand new; nothing like it has ever been altempted before. Prior to the appearance of this axis, gour changes in other axise of the kind have been under manually by means of a lever similar to the ordinary transmission gear-set lever. In this new axis, which is illustrated herewith, the gear changes are unde with the aid of magnets controlled by a small button placed conveniently at the driver's hand. Hence, to obtain either high or low gear requires merely the depression of the button, no other movement being required.

In construction, the new axie is much like the orthon pattern of rear axie except that it has two bevel rings and two bevel plutous instead of one of each lone of the heavy plutous is connected to a solid shaft which is curried on hearings inside a hollow shaft to which the other bevel plutous is attached; the generate constantly in much and the magnets operate constantly in much and the magnets operate

Just how much the new axis may be expected to decrease feel consumption may be anthreed from the fact that the use of the high sear rule increases the range of part 42 per cent with the engine revulutions remaining constant. For instance, with the engine turning at 10 proveolutions a minute and the low goar in use the speed of the cer will be approximately 21 unles an hour, whereas with the high even in use the car speed will be approximately 30 miles an hour. In other words, the car will travel unless further on a given amount of fuel with high sewr in use that it will with the low goar in use. The high sear always a final ratio of 2.5 to 1 and the low gear a ratio of

The lucrosse in mileage, of course, is supplemental to decreased were and tear in the parts, due to the slower speed at which they operate when the high gear is in one. Also, engine whreation, which always countrates a measure to the life parts, is matrially reduced at high car aposts. The new arise is being used as standard equipment on all of the cars produced by the manufactured for the 1914 seems.

## A Test of Milking Machines

There recently took place in England a competitive to of mitting machines under the acquires of the Royal agricultural Society. Thirteen machines were entered. The winning machine, manufactured by swedish company, is built on the vacuum or suction principle. The milk is conducted by transparent collisional control of these to the containing vessel which is hung under the cow by means of a girth, and the milking is performed in manch the same way as will nother vacuum machines. While a vacuum or suction principle machines were ruled out after the first class of the same vacuum or suction principle machines were ruled out after the first trial, and that after the second three more were eliminated, the remaining two taking first and second

Nh, 1999, by President Tuft on the creation of the office, has resigned the position to take effect August Illet, 1913. Mr. Billings' service as First Assistant Commissioner, follows that of Assistant Commissioner, to which position be was appointed June 1st, 1997, by President Boncevelt, and a torn of service in the Pate ant Office extending continuously from his appointment as Fourth Assistant Examiner ander Ctvl Service on May 24th, 1809, with the exception of a short period when he accepted a commission as ensign in the Navy for service in the Patentrous and efficient officer and resigns the service to enter upon the practice of patent law in New York Ctv.

## Distillate Gasifiers for Motor Vehicles

Tille cost of fuel for motor trucks is cut to less than Indiff by the use of gasilters, extendively employed on commercial vehicles in Culifornia. The gasifiers are placed on the engine in such a way as to heat the cartureter nature; just before it is delivered to the cylinders, and in this way it is possible to secure excellent results with distillate. The gas is delivered dry and hot and ready for combastion with the same regularity as gasoline, and carbonization, caused by imperfect combustion, is practically elliminated. The cost of gasoline in Los Angeles is 17 cents a gallon, while distillate soli at only 7 cents a gallon and delivers 25 per cent more power. This effects an enormous saving to owners of motor trucks in the course of a year. Owing to the odor of distillate, it is not used on ptenarre vehicles.

Two types of gardiers are in common use in California, both based upon the same principle. One consists of a large casting boiled to the engine, inclosing
part of the exhaust. The coasting is perforated as that
the air which enters the entiructer passes over heasted
metal before being combined with the distillate, and
the nixture from the carbureter passes vibrough the
hot cylinder on its way to the cylinders, being delivered
at a temperature of 100 degrees. The other consists of
a cylindrical brass custing filled with tubes like a
holder. This is attuched between the entrureter and
the cylinders and connected with the exhaust through
a leight of flexible tubing. The air is not hoasted before entering the carbureter as in the other type, but
the mixture passes over the boasted tubing before reaching the cylinders. In using both types, an auxiliary
tank of gasoline is curried for starting the engines,
though it is not required for starting, while the gasi-

## A Portable Controller for Electric Cranes

IT is reported from abroad, that a new method of controlling crauses has recently been introduced ou the docks of the Munichester ship canal and at other points in England, in which the crane controller instead of being operated from the cab of the crane as heretofore, is portable, weighing but sky or eight pounds, so that it can be suspended from the shoulders of the operator, who can then occupy an advantageous position with regard to the work, move about and see what is taking place in the hold of the vessel. In the past he has had to depend on signals given by a man standing at the hatchway. The controller is provided with a past swift. To stop in an emergency, it is uccessary for the operation only to hit the knob of the push awtich to bring the crane motor to a stop. The invention not only facilitates the operation of the crane, but effects a material economy by disponsing with the necessity of the signalman employed at the lintelway.

## Strange Headlights from France

A NEW automobile beadlight has just been put on the market in France, which represents a radical departure from present designs. As will be seen from the accompanying litherations, the imap has the shape of a human eyeball and turns to its socket in exactly the same numer as the eye in its support. Two small clamps, controlled by thumbscrews from the interfor of the ear, hold the lamp in position in may desired direction, while the handle lised is used to turning the light may be the spot of the ear, hold the lamp in position in may desired the light may to the spot they are needed. Signposts at the side of the rand or the low-lying intentones are thus brought within reach of the rays, while in their lowest position they even throw light into the hood, lighting up the motor, magneto and carbureter. By removing the two small clamps entirely, the whole lamp can be taken out of the socket and itsed as a "trouble lamp" inside or outside the machine. It is the invention of a Fracel senjmer, Educard Chamsool.

Jake T

## Notes for Inventors

A Wave Motor for Propelling Be Patent No. 1,066,896, to John Frame of Searsport, Maine, shows a boat equipped with a motor so constructed as to drive the propeller shaft of the boat upon the rise and fall of the boat by the action of

Four Signature Writing Machine Patents.—A series of four patents, Nos 1,066,115 to 1,066,118, inclusive, has een issued to Frank Amos Johnson of Jersey City, assignor to Signature Comof New York city for machines for writing a number of signatures and duph cates, at the same time.

A Glider Instead of a Roller-skate natent has been issued to John H. Koenig New York city, No. 1,067,039, for a glider which is in the nature of a skate having relatively flexible portions for the sides thereof with curved gliding surface somewhat similar to the "domes of silence" employed on furniture

A Tubular Corrugated Rallroad Tie. Ernest J. Pettegrew of Wayside, Neb., has secured a patent, No 1,086,943, for a metallic railway tie which is in the form of a tube continuous throughout and has corrugations extending entirely around it between the rails and also outside of the rails with the intermediate spaces for receiving the rails free of corrugations.

A Brake Shoe Patent.—In patent No. 1,066,119 to Harry Jones, of Suffern, N. Y , sesignor to American Brake Shoe and Foundry Company of Mahwah, N. J. is shown a flanged brake shoe in which a metallic body portion contacts with the tread of a car wheel while a flanged portion of non-metallic material is provided to contact with the flange of the wheel.

A Novel Method of Producing Ozonized Air. -A patent, No 1,086,065, has been issued to James Todd of Sewickley, Penn, for a method of producing so-called ozonized air. The amount of air passing to the ozonizer is varied according to the temperature of the surrounding atmosphere, and is reduced as the temperature ris and increased as the temperature falls.

Advertising Device to Create Illusions. George H. Schanck of Libertyville, Ill., has secured patent No. 1,066,850, for an advertising device which simulates perotion and employs a revolving wheel, suitably driven, and having arms which are proted to swing and upon which balls roll back and forth in such manner as to increase the effect of the device being a perpetual motion machine.

A Combined Bottle Stopper and I George J. Dysinger and Johnnie C. Haskell of Galena, Ore , in a patent, No. 1,060,172, present a staple embedded in a bottle stopper and a separate part formed from a single length of wire and bent to provide a hold for use in pulling the bottle, the puller being connected with the stopper stable and such puller also having arms formed to engage with the shoulder on th bottle neck to hold the stopper in the bot-

French Kitchens .- It is reported that a leading merchant of Havre recently made in his store windows a display of his idea of equipped kitchen for a family in comfortable circumstances. While it has been conceded from time immemorial that the French nation leads the world in culmary skill and economy, it is a tribute to the ingenuity of Americans that six articles of American manufacture were included in the equipment of the ideal kitchen displayed by this French merchant These six articles included an ice-cream freezer, an ice pick, a hashing machine, a cake-baking mold, a coffee pot and a broom.

A Gyroscopic Dumbbell.—A gyroscopic dumbbell hav been patented, No. 1,058,786, to Burt L. Newkirk and Otto S. Zelner of Minnespolis. The device includes a dumb bell with a shaft journaled in it and gyro scopic disks on the shaft providing an respire disks on the snar providing an exer-eising device which is free from attachment to any apparatus and when held in the hand is capable of offering resistance to motions

made by the user whenever such n would tend to change the direction axis or axiss of the rotating masses. ch meticos

Planting Artificial Hair in the Se Aurel Popovies of Torok-Kanlson, tria, has patented, No. 1,059,831, a m m, Å116 of imbedding artificial hair in the scalp. A retaining element is applied to the hair and a minute cavity is pierced in the scalp. The end and the retaining element of the hair is inserted in the cavity below the surface of the skin, so that hairs can be planted in the skin with, the inventor claims, such a degree of perfection as to render the artificial nature of the hair covering thus produced completely unnoticeable

An Improved Brick Tie.—Consul Van Sant of Dunfermine, Scotland, reports that a builder in Dunfermline has recently invented a new type of wall tie and that invented a new type of want the and time, while the tie formerly used gripped but two bricks, the improved tie will catch a half dozen bricks giving additional strength to the wall, requiring fower ties and resulting in a considerable saving in the used in large operations. The so be seen before the wall is plast The tie and thus avoids any dispute about using fewer bricks than the number specified by the architect.

Another Hulett Conveyor Patent.— George H. Hulett of Cleveland, Ohio. assignor to the Wellman-Seaver-Morga Company of the same place has patent stem for unloading cars into ves a system for unloading cars into vessess.

This includes appliances for tilting the car and dumping its contents. A motor-driven, automatic-dumping car receives the load from the first car and an elevator the load from the first ear and an elevator lifts the automatic dumping car to an elevated treatle which has a chute into which the contents of the dumping car are discharged. The dumping car is returned to its starting point by a suitable downwardly inclined track. The patent is No. 1,066,015.

Egg Packages .- Think of a gross retaggs.—Inink of a gross of million broken eggs. Such is the yearly erop of broken eggs marketed in New York city alone. Of course, this includes York city alone. Of course, this includes the breakage in packing, the breakage in transit and the breakage in unpacking. It is probable that the breakage in packing and unpacking equals that in transit. It is reported that the Department of Agriculture is investigating the subject. The problem presented its an interesting one problem presented is an interesting one to inventors. The package of course, must not be too expensive and the packing and unpacking operations must be capable of accomplishment with facility as well as

Patent and Trade-mark Registration in the Philippines.—Under an act passed at the last session of the Philippine Legis lature any patent or trade-mark register in the United States Patent Office, up being filed in the executive bureau of the Philippines and the fee for such purpose paid shall receive the same protection ed in the United States, and persons infringing such patent or trade-mark shall be liable to the same penalties. It is provided that the rights of property in patents and trade-marks secured in th Islands under the Spanish Laws shall b respected as if such laws were in full force

A Sanitary Milk Bottle. -Realizing objections from a sanitary point of view to the ordinary milk bottle, Merritt G. Seamans of Atlanta, Ga , has patented a lining for nulk bottles which may be of paper or other suitable material and can be slipped down into the bottle and will be expanded by the force of the liquid inserted therein and has a portion which is bent over and down along the outer side of the lip of the bottle. A closing disk may be inserted as manal.

Talking Moving Pictures,-Henry Theo Taking Moving Pictures.—Henry Theo-docrope Regester Webb of Baltimore, Maryland, has secured patent, No. 1,026.— 324, in which motion picture and sound-

seing devices with the drive member produce unison of action between as to pro to as a produce unusus or souson network ble pleture device and the sound repro-tion without change in the relative speeds under fluctuations of speed derived from the drive member.

A Toggie Spoke Spring Wheel.—In patent No. 1,065,386, to Frank J. Nicolet of Stockdale, Ohio, is shown a spring wh in which sectional spokes composed of two sections pivoted together at one end and nivoted respectively at their other ends to the rim and hub are arranged to connect the hub and rim. Springs are disposed to act on the outer sections in such manner as to permit the wheel to yield under pressure and at the same time tend normally to hold the hub at the

Synchronizing Motion and So production.—Edward H. Amet of Redondo Beach, Cal., has secured a patent, No. 1.065.576. in which is shown a motion oture machine with a film provided with perforations on lines between the picture sees and means are provided to supply seumatic pressure on the picture ribbon This procumatic pressure operates through the perforations in the picture film to actuate electro-pneumatic means which control the operation of the sound reproducing machine, thus securing a sychronou

Advertising Novelty.-Dorsie A. Loh of Woodlawn, Pa., has patented, No. 1,-061,302, as an advertising novelty, a mega-phone which is adapted to be collapsed into pane which is adapted to be collapsed into the form of a fan and to be held in such form so that it can be used as a fan, the megaphone having a telescopic mouth-piece which may be adjusted to serve as the handle of the fan.

New Needle for Talking Machine.—In patent No. 1,061,408, to Percy B. Rug-gles, of Wyoming, O., is shown a reproduc-ing needle for talking machines which is made from the shaft of a feather with the barbs removed, such shaft possessing an outer shell with a softer interior, the structure being artificially hardened to render it more desirable.

A Trick-playing Card .-- A playing card which can be made to show clubs or spades at the will of the holder is illustrated in a patent, No. 1,061,576, to George W. Walter, of New York city, assignor to Edgar G. Walthall of same place. The card comprises a face card having clubs marked thereon and openings adjacent to the clubs and forming with the clubs the outline of spades and a sliding card which has por-tions the same shade as the clubs and other portions the same shade as the stubs and other portions the same shade as the ground of the face card and the sliding card can be moved to place either of said portions in register with the openings in the face card.

A Removable Dental Bridge.—Harry A. A semovable bental Bridge.—Harry A. Gollobin and Newton A. Bornstein of Newark, N. J., assignors to The Dental Denture Improvement Company, of the same place, have patented, No. 1,062,233, a removable bridge for teeth in which the bridge has a bridge to teem in which the bridge has flat split tongue or resilient material, the branches of which engage within a recess in a crown portion of a tooth, so that the bridge will be securely held in use and yet can be removed when necessary.

A Steinmets Incandescent Lamp.-The well-known inventor, Charles P. Stein-metz, assignor to General Electric Company, has patented an incandescent lamp ent, No. 1,062,305, in which an meandescent conductor is disposed within an evacuated envelope and supplied with cur-rent and means provided for furnishing gas-absorbing material during the opera tion of the lamp by the disintegrating tion of an electrical discharge taking place across a portion of the evacuated space.

Nickel-in-Slot Telephone System .- The dore Crapo, of New York city, assagnor to George Reguester Webb of Baltimore, Automate Electric Company, of Chicago, Maryland, has secured patent, No. 1,120;- as assigned of John Erickson, also of Chicago, Charlest Company, of Chicago, Charlest Company, of Chicago, Particle Company, of Chicago, Particle Company, of Chicago, Particle Company, of Chicago, Particle Company, of Chicago, has secured a patent, No. 1,026,287; relatively different appears and a divier is provided for establishing a talking circuit provided in connection with a governor-body country of the Company of the Compa

mid lines is arranged in com means for rendering the talking direct inoperative and mean ne are also prov olled by depositing a plurality of coins in the coin-collecting device, for rendering the talking circuit operative.

A Combined Smokestack and a Life-A commune smoonestack and a late-preserver.—A life-saving device is shown in a patent, No. 1,081,209, to William Monroe White of Milwaukee, Wis., in the form of a ship stack which is detachable and is formed with an air-tight compart ment. As shown, the stack is flattened transversely and has an air-tight compartment at each of its two more flexed sides and the stack when detached and in the water may operate as a life-preserver or life-raft, its capacity varying with its sise.

A Cover that Operates a Valve.--In patent No. 1,062,209, to John L. Williams, Jr., of Jackson City, Tennessee, for a sani-tary drinking fountain, a hinged cover is tary drinking fountain, a miged over a arranged to close the drinking oup and this cover operates when opened to open the supply valve, such valve being closed auto-matically by a spring when the cover is closed so that the water only flows when the cover is raised by some one desiring a

## Legal Notes

Patentability of Process as Related to Apparatus.—The Court of Appeals of the District of Columbia in re Rowe has susof Patents in rejecting the application and held that the claims were properly refused on the ground that they are merely siments in different words of the inven eovered by applicant's prior apparatus, the Court saying: "An invention is not made different by the mere fact that one is disclosed in a claim for an apparatus patent and the other one in the form of a method or pro

Employer and Employee.— The case of Jameson and Yesbera v. Ellsworth, de-cided by the Court of Appeals of the Distriet of Columbia, brought up an interest-ing point. The appellant Yesbera was the president of the Yesbera Manufacturing Company, while Jameson was a fore-man of the company, and the appellee Ellsworth general manager of the company at the time of the conception and reduc at the time of the conception and reduc-tion to practice of the invention. The Court stated that as between Yesbera and the appellee Ellsworth the prosump-tion of inventorship was in favor of the employer, but that before such rule might be invoked, it must appear that the employee was engaged in perfecting a device under the general direction of the employer; that appellee was not employed for the purpose of perfecting this or invention and that hence it must be affirma-tively shown that at least the broad idea was disclosed to Ellsworth by Yesbera before the presumption referred to would attach

The Commissioner's Right to Review The Court of Appeals of the District of Columbia in the case of Moore, Com-missioner of Patents, et al. v. United States ex rel. Chott. has confirmed the Commissioner's right of review after favor-Commissioner's right of review after favor-able decision by a subordinate tribunal. The case arose in a pocular way, the Board of Ezamiser-in-Chief on appeal reversing the decision of the Primary Examiner and deciding the claims to be patentable, whereupon the Primary Examiner acting by authority of the Commissioner, me an additional investigation, cited additional patents and the Commissioner took up the case and approved the action of the Primary Examiner. The applicant sought the aid of a mandamus wit in the Supreme Court of the District of Columbia and Mr. Justice Barnard of such Court granted the writ to compel the issue of a patent to the applicant. On appeal the Court of Appeals has held that the Comcourt of Appears has need that the com-missioner has authority to review the appli-cation and if in his opinion the alleged in-vention is not patentable to refuse a patent

INQUIRIES

The Heavens in August

(Concluded from page 90.) in fact, the two planels are in conjunction on the 24th, and little more than 1 degree on the seth, and fittle more than I degree apart. Saturn is the farthest south, and is a little the brighter of the two, while Mara is moving eastward more rapidly, and so overtakes the larger planet. This conjunction will be a very pretty sight, but one must get up in the morning to

see it. Finally, Neptune is in Gemini, lately past conjunction with the Sun, and ob-servable only in the morning. On the 29th he is in conjunction with Venus, being but

18 minutes north of her.

The Moon is new at 8 A. M. on the 2nd, in her first quarter at 11 P. M. on the 2nd, in her first quarter at 11 P. M. on the 8th, full at 3 P. M. on the 16th, in her last quarter at 7 P. M. on the 24th, and new once more at 4 P. M. on the 31st. She is nearest the Earth on the 3rd, and again on the 31st, and farthest away on the 18th. As the new Moon at the end of the month almost coincides with the time of perigee, unusually high spring tides may be expected.

While completing her circuit of the skies

the Moon comes into conjunction with eptune on the 1st, Mercury on the 2nd. Jupiter on the 12th, Uranus on the 15th, Saturn and Mars on the 26th, Venus and Neptune on the 28th, and Mercury again on the 80th

todos, a diminutive flying fish found to Lake Tchad, in Africa, merits especial attention because of its peculiar structure and singular habits. It owes its name to the formidable array of teeth which cover its tongue and the principal which cover its mouth, in addition to the jaw-bones proper. The dorsal fin is very short and is placed near the long and pointed tail. The folding pectoral and ventral fins are very large, and the latter ventral fins are very large, and the latter terminate in fine filaments. These organs suggest great powers of flight, and, as a matter of fact, M. Fourneau, of the Lake Tchad mission, has seen the partodon rise from the water and, by flapping its pectoral fins, traverse distances of 5 to 20 yards, or more. These are long flights for a fish only two or three inches in length. In the aquarium the Pentodon remains quietly at the surface in the atti tude shown in the photograph, which, un fortunately, cannot reproduce the gorgeon livery of this butterfly of the water. The back is clive, in some specimens crossed by transverse dark bands; the belly is slivery yellow, tinged with carmine; the fins are bright pink dotted with violet brown, and the tips and inner surfaces of

the pectorals are violet-hued.

## **Trade-Marking a Famous Motor**

Engrave on the tablets of your memory this trade-mark. It is the stamp of a good motor and a good motor is the solid foundation of a good automobile. The dictionary makers realized this, when they defined an Automobile as a "Motor Vehicle; all men who motor acknowledge it; and more than 50 of America's leading motor vehicle makers proclaim it by building their cars upon the sure groundwork of the Continental Motor.

- I A weak foundation has ruined many a costly edifice. Down to bed rock must go the substructure; down -in the case of a motor vehicle-to the hard and fast assurance of a motor with power, with speed, with certainty of service, with sales prestige, with long years of life-span.
- The name of the motor-symbol of power-reveals the character of the car. For the motor is the key to the whole construction-the costliest and most vital factor. Every motorist should know this, and Continental advertising is going to make this knowledge public property.
- Continental motors date back to 1903. They have perennial youth in design-the maturity of age in experience. Over 75,000 are now in usedeveloping, daily, more than six times the horsepower taken from Niagara. Best known cars cars that have conquered the world's markets - have swept to success carrying the Conti-
- To the companies making these cars, their engineers as well as our own, belongs the proud distinction of having made "Continental motors America's standard." For the counsel of these many engineers, some of whom not only stand as leaders in their profession but are individually known to every American who reads, has had much to do in the final perfecting of Continental motors.
- These are the far-seeing, level headed men who, building for the competition coming, have already specified over 40,000 Continental motors for 1914
- ¶ Not made to meet a price, not built to shatter records of quantity, Continental motors are constructed to fullfill a service ideal - to be a true foundation for a worthy motor vehicle.
- ¶ For this we trade-mark our

and the metal-worker in general, read the following Scientific American Supplements: 1112, 1384, MUNN&CO. Inc. 1481, 1622, 1610, 1434, 1533, price 70 cents FUBLISHERS by mail. ¶ Order from your newsdealer or from 361 Breedway, New York

ve description. The male fish builds a tiny nest of foam, into which he ences the female by assuming a nuptia livery of the most brilliant coloring, but as soon as she has deposited her eggs, he drives her away and takes upon him the duties of the mother and nurse, to which he devotes himself sealously until his offspring become able to find their food This maternal instinct of male is strongly developed also in the chanchito (Heros facetus). One of these curlous fishes in the aquarium of oue of curious innes in the adartum 5 dec or my friends had a brood of sixty little ones, which he defended valiantly, promptly attacking and biting any finger that was rashly plunged into the water The worms and raw beef on which the young fishes were fed were chewed fine by the father, and an amusing spectacle was ented by the little ones taking their food from their father's lips.

Some exotic fishes are even more bril-liant in coloring than those described above. The orange-colored cost of the Scatophagus argus, for example, is adorned with artistically arranged dots of velvety black, and a beautiful azure bead marks every scale of the Brazillan (Sch-

It might be supposed that these living s of tropical waters require constant e. Ou the contrary, they can be kept without trouble in an ordinary dwelling or apartment. Although M. Lefèvre, who propagates these exotic fishes on a large scale, has installed his aquarlums in two hothouses, and Mme, Kuhnt conducts an elaborate pisciculturai establishment near Berliu, M de Visser keeps his fishes in tanks of about 25 galions capacity ou a veranda, where speci very different dimensions and origin dwell

The proper water temperature (about 70 deg. Fair for most species, and 80 deg Fahr, for a few others) is maintained. usually, by means of an alcohol lamp con-tained in a nickel-plated cylinder, which is ballasted so that it floats in a vertical ssition with its open top, which is cov ered by a fine wire grating, aloue emerg ing from the water. The aquarium may also be heated by lamps placed in a lower unpartment, separated from the tank by double partition. Large and pugnacion fishes, and some others at the breeding n, are confined singly in gla-In marked contrast to domestic fresh wa ter fishes, which do not thrive in captivity unless they are kept in running or frequently renewed water, these exotic fishes may safely be kept for mouths in an aquarium without a complete change of water. It is sufficient to draw off one teath part of the water every week, and to replace it with an equal quantity of fresh water of the proper temperature. Adequate aeration, however, is essential. This may be effected very easily by placing in the bottom of the aquarium the end of a rubber tube, communicating with a sed air cylinder, in which a pres sure of three atmospheres, as indicate an attached manameter, is maintained by means of an automobile tire pump. The immersed end of the tube is closed by a thin membrane, which is traversed steady stream of minute air bubbles.

The sandy bed of the aquarium is plant d with Vallimeria, Miriophyllum and other green aquatic plants which are use fui as weii as ornamental, as the in oxygenating the water, afford shelter to the fishes and facilitate their reprodu

The cultivation of exotic aquartum hes deserves every encouragem it is not only a source of enjoyment, but it offers a field for scientific observation of the curious and still imperfectly studied habits of these pretty little creatures.

uclear division figures, with various kinds of outgrowths, had been described by Leduc in earlier writings, together with the comotic growths of varigesting molds, sea-weeds, toadstools Both series of phenomena were re ed to and illustrated in the Scientific AMBRICAN, September 9th and 23rd, 1911.
Fig. 4 is a reproduction of one of Leduc's "artificial" nerve cells, shown alongside of a ganglionic cell (Fig. 5) prepared by De-moor according to Golgi's method. Leduc's "cell" was produced by placing a "seed" consisting of two parts of copper sulphate and one part of cane sugar in a solution of ferrocyanide of potassium. A precipitate of copper ferrocyanide is formed on the surface; this is impervious to sugar, but water is readily absorbed through it, leading to "growth" in all directions, the final form depending upon the precise distribution of the particles of sugar and of copper sulphate in the grain, upon variations in the density of the medium, etc.

Much of the argument in the book is devoted to showing that the lines of dynamic discharge are essentially the same in an organism and in organic media. To this end illustrations are derived from a comparison of electric discharges and crystallization figures with ferus and other plant structures. Fig. 8 is the elec-tric discharge resembling a leaf; Fig. 10, an electrolytic pattern suggesting a fern frond; Fig. 11, a crystallization of ammonium chloride in gelatin suggesting plant forms; Fig. 9, four successive stages in "karyokinetic" figures produced by diffusion; Fig. 12, a modifi diffusion currents by contact of a glass diffusion currents by contact of a name rod, illustrating irritability; and Fig. 18 shows "negative heliotropism" of diffusion currents of india ink in sait solution.

With wonderful patience and ingenuity Prof. Leduc has taken up in turn the mmonly recognized characteristics of living cells—their structure, their absorption of nutrients, their nuclear division their irritability, the circulation, the relation of temperature to function, their transformation of energy—and has reproduced each phenomenon in turn in a aration which is admittedly "non-living." But has he thereby made an approach to the artificial synthesis of life? All that we can learn from these experiments is as evident in the world of living things as in the world of non-living; that motion here is along the line of least resistance as it is there; that the mechanics and th electrics and the chemics of living colls are the same as those of non-living sas

The chapter on the origin of life and cous generation is a same statement of the problem, and to it Dr. Leduc points out the logical necessity of assum-ing that life not only did originate "spontaneously"—in a scientific sense—but may do so again under suitable conditions. He also points out the evasion of the issue involved in such theories as that of Arrbenius in regard to the extra-terrestrial

Whether the methods of Ledne ever whether the methods of Leduc ever reach the bottom of the problem or not, these experiments have their value in clearing the field of much conjectural rubbish and confusion; and as for the synthesis-that has not yet reached the experimental stage.

## OTOR WORKS, 2070 N & **BRISTOL'S RECORDING**

neters, Pyremeters, reters, Wattmeters, Tachometers and 

other members of the atmost tion. He needs to know, for example, the relation of the winds to the isobars at various levels in a typical cyclonic disturbance. It is a distinct advantage to him to learn that, while at the earth's surface to learn that, white at the earth's surface the 'winds blow spirally inward toward the center of a depression, at the mile-level overhead they are no longer inclined inward, but blow in such a direction that the isobars on the surface weather map correspond approximately with the n of a free balloon at such a level. Thus aeronautical meteorology, which is a science of three dimensions is vestly science of three dimensions, is vacty more complicated than marine meteor-ology, which is a science of only two. Let us repeat, however, that in spite of the magnitude of the tasks imposed

upon it, aeronautical meteorology has already reached a stage of great practical utility. A single illustration will make this clear. Suppose plans were on foot to establish a regular airship service across the Atlantic, where would be the most favorable route? Meteorology is ready to answer this question. For the westward journey there is one region, and one only, in which the winds are favorable through out the year, viz., the trans-wind best. For the eastward journey a sea-level wind chart, might suggest the advantage of a more northerly route, in the sone of "prevailing westerlies." Accology, however, can better this suggestion. The winds of middle latitudes, although westerly in terms of averages and resultants, are actu ally subject to the vicissitudes attending the frequent passage of cyclonic disturb ances. There is only one region in which there is a tolerably steady drift from west to east, and this is the zone of the antitrades,3 lying vertically over the trade winds. Hence the first transatiantic airships will probably sail from southern Europe to the West ludles at a low level and return in the same latitudes at a level a few thousand feet higher. The tropical hurricanes that occasionally invade this region during the late summer and early autumn will be announced by wireless telegraphy from the meteorological bureaus, and the aerial liners will give them a wide berth-or possibly rise to the upper level of the storm itself and take advantage of the outflowing winds at that level to get away from the storm center. Aerologists have now been at work for several years sounding the air above the trade-wind belt. The trades are found to be quite shallow, and their depth varies

be quite annion, and their depth varies considerably with latitude. We have not space here for even the most summary digest of the science of aeronautical meteorology, but must limit ourselves to an enumeration of its principal subdivisions. We have already de-voted considerable space to the wind, as the subject of capital importance. Under this head let us add that valuable statis tics have been compiled as to the varia-tion of the force and the direction of the wind with aititude (see, for example, Fig. 3); that the average windiness of various places on the earth's sur-face has been determined, in order to point out the most favorable locations for aerial harbors and aerodromes; that the relation of the winds at mederate altitudes to the topography of the land has been worked out in great detail; and that ingenious forms of apparatus (e. g., the vertical anemometer and the pilot-balloon) have been devised, to supplement the ordinary anemometer and wind-vane for aeronautical purposes. The elaborate investigations on wind pressure and the like carried out in aerodynamic laboratories, belong to engineering rather than

to meteorology.

Temperature is a very important factor Temperature as a very important nation.

In ballooning; less important in aviation.

Here, agaik, aerology has gathered a great fund of information. We know not only the normal temperature gradients in the atmosphere, but also under what condi-

tions these gradients are likely to be in-terrupted or rywersed. The typical ver-tical and horizontal distribution of tem-perature in cyclubes and anticyclones— subject concerning which very erromeous opinions formerly prevailed—has now been approximately determined.

Ro with the other meteorological elements. Each of them, thanks to the advent of accology, has now been studied for several years from the three-dimensional point of view, which is the point of view of aeronautics.
Of the special storm warning

for aeronauts recently established or pro-jected we have not space to speak. They are the logical corollary of the science of aeronautical meteorology, and will soon be commonplace institutions the world

## Device for Detecting Flight of Mosquitoes By L. E. Haskell

A N instrument for detecting the direc-tion of flight of adult meaguitoes has been invented by E. F. Quimby and has been put in operation with a great deal of success on the Isthmian Canal Zone. Mr. Quimby, division inspector in the De-partment of Sanitation on the Canal Zone perfected his device for the purpose of ridding the more remote parts of the zone from mosquitoes.

The device consists of a metal fram holding four plates of glass each 12 by 12 inches in size, placed upon a tripod. The angles to one another so that when the inent is set up, they point north, eas

Device for detecting the flight of

south and west. To catch the mosquitoes, a cost of tanglefoot, composed of one half pound of rosin to one liter of castor oil, is prepared, and when applied to the glass to prostically transparent.

Many interesting and important fa regarding the habits of the mosquito have been learned. It was found that the adult mosquito flew on the quarter of an eigh-teen mile an hour wind; that the evening flight occurred between 6:10 and 7:10 o'clock; that there was a complete lull in the flight after 7:10 o'clock; and that there was a return flight between 5:50 and 6:40 o'clock in the morning, also on the wind's quarter.

The instrument has proved to be us ful in locating breeding places by elimin-ating the area facing the plates that do not show a catch. It has established a not show a catch. It has setablished a means of finally exterminating measur-tors on the Canal Zone. The device points out the direction of the breeding places; a thorough search; the discovery or awanny ground or pools of stagnant wa-ter; a little kerosene; and the breeding

THE RANGE

NA PRIOR OF

Navy to Determine Longitude by Wireless; also Speed of Hertzian Waves

By Louis E. Browne

O'HE of the most important duties of the United States Naval Observatory is is the exchange of time signals with naval hydrographic surveying parties, for estab-lishing the iongitude of points on the coasts of Cuba and Central America, which those parties use as bases of their surveys. Formerly these signals were exchanged by telegraph or crose, out of acc radio-telegraphy has been resorted to for isolated stations without cable connec-tions. This method seems to offer such advantages that the Navy Department is contemplating the abandonment of the belegraph and cable signals.

The Naval Observatory was the first in stitution in the world to have its time sig-nals regularly transmitted by wireless, thus enabling ships at sea to correct their chronometers and thereby more accur-ately to determine their longitude, but the French have become pioneers in the method of exchanging radio signals between shore stations, for the determina-tion of differences of longitude.

In view of the approaching completion of the powerful wireless station at the Eiffel Tower in Paris, the French government inaugurated an international conferment inaugurated at international contents of each of consider questions of regulating radio time signals. The United States was represented by Commander H. H. Hough, the Naval Attaché at Paris, and Prof. A. Hall of the Naval Obervatory.

Recognizing the importance of deter mining the difference of longitude between Washington and some point on the Euro pean continent, in order that it may be used as a base for hydrographic and military survey on this continent and the islands of the Caribbean Sea and the Pacific Ocean, the Navy Department pro-posed that time signals be exchanged by the powerful Arlington wireless station in Washington and the Eiffel Tower station in Paris.

Preliminary investigations are now go ing on, and while an approximate determinution of longitude is expected to result from them, the principal benefit to be derived is the familiarizing of officials of both nations with the methods to be used, to enable them to decide upon a plan of operation for the final tests which will be made this winter. Two instruments, especially designed for the astronomical work, will be of the highest excellence. The very fine meridian circles which are The very fine meridian circles which are installed in the Naval Observatory will be cast aside; for it is desirable that the in-struments used in Washington and Paris should be as nearly identical as science can make them and of such size that they may be interchanged, so that an observer here, after a series of observations lasting several weeks, may take his instrument to Paris and repeat the operation there, the observer in Paris transferring his instrument to Washington. In this way all instrumental and personal errors will be practically eliminated.

As soon as this determination is com-pleted the Washington Government contemplates a determination of the differ-ence of longitude between Washington and ence or iongitude between washington and some point on the Panama Canal Zone and other important points on the Cen-tral Asserican coast. The survey of the Panama Canal Zone, relatively to Europe as well as the United States, grows more and more important as the date for the opening of the canal approaches.

opening of the canal approaches.
Connected with this work, and fully as important to the scientific mind, is the problem of determining the velocity of propagation of the Hertzian waves. Although this phase of wireless telegraphy though this phase of wireless telegraphy has greatly interested scientists the world over, and many theories have been adyrained, so far no frue determination has own, here attempted. It has been conseil, end that the Harristan waves travel, at about the speed of red calcium light, than for whose 188,000 miles per second. ## The Ten Greatest Inventions of Our Time

We hear much of the great inventions of the past—the telegraph, the sewing machine, the telephone, the reaping machine, photography, Bessemer and open hearth steel, the steam engine and the phonograph. Yet the inventions of our own time are as epoch-making and as dramatic as these.

Perhaps because we have become accustomed to the use of the old machines and discoveries, perhaps because the achievements of latter-day inventors succeed one another so rapidly that we are not given much time to marvel at any one of them, we have not fully realized how stirring and wonderful are the products of modern ingenuity.

Only five years ago the man-carrying aeroplane made its first public flights; only the other day hundreds of passengers on a sinking ship were saved with the aid of wireless telegraphy. At least a dozen inventions as great have been perfected in our own time, and all of them have made a man's work count for more than it ever did before, and have made the world more livable than it ever was.

Why should we not tell the story of our own deeds? Why should we not review the industries created by men who are still living, men whose names will go down into history with those of Watt, Morse, McCormick and Howe?

That was the underlying idea of the November Magazine Number of the Scientific American. We knew that the "ten greatest inventions of our time" was a big subject when first we planned the number, but how big it was we never realized until we surveyed the field of modern invention.

Then we saw how astonishing was the progress made in our own day, how much mankind had benefited by the inventions of great modern intellects. We began to appraise inventions, to weigh one against the other, and to determine in our own minds which ten had contributed most to human progress and happiness, which were really great pioneer inventions, and which merely remarkable and valuable improvements on successful past conceptions. There were so many achievements to consider that it was hard to arrive at a definite conclusion.

The upshot of our own thinking has been to leave to our readers the decision

## What Are the Ten Greatest Inventions of Our Time, and Why?

For the Three best articles on the subject, the Scientific American offers in the order of merit, three cash prizes:

First Prize: \$150.00 for the best article Second Prize: \$100.00 for the second best article Third Prize: \$50.00 for the third best article

See page 86—this issue, for conditions of the

travel either 100,000 miles a second faster

or a few theighand nulles allower. The difference of lengthrade of two places will be determined by the difference in time, and this is determined to the observations of so-called clock stars over the meridians of the two places, the greatest care being taken to eliminate all mechanical and personal errors. Everything being ready, star observations will be made to determine the errors in the clock or chromometers to be used at each place. The errors of the two timekeepers being known as the result of these observations, they are then compared by means of wireless signals to determine the difference in time between the two places.

Both clocks will be regulated to best slightly different times; for instance, one will best mean time seconds and the other siderest seconds. This makes the bests of the clocks coincide about every six minutes. If then the clock-leate, in Paris, close the circuit of the wireless apparatus, they will be transmitted through the ether and read in Washington at the Arlington wireless statutos. The observer in Washington will be equipped with a double bend telephone, receiving the radio signals in one sar and the bests of the Washington clock in the other. In this way he can tell when the coincidences occur, and by means of conventions arranged beforehand between the two stations the exact time of the two stations the exact time of the two stations the exact time of the coincidences will be known at each station.

In this way it is expected to determine the difference in time and consequently the difference in longitude to within 1/100 of a second. The siderent second being less than the mean time second by 8/1000, the method of coincidence provides a means of detecting that small fraction of time if one can absolutely tell when the coincidences occur.

conneners over.

The process is then repeated, Arlington sending and the observer at the Effect Tower receiving the beats of the Washington clock as automatically repeated by radio-tolegraphy and beats of the Paris clock in the other ear.

Paris is roughly 3,000 miles from Washington. Vising the estimate that the Hertian waves travel with a velocity equal to that of light, if would take 1/00 of a second for the wireless flash to make its trip across the occun and would take 1/00 of a second for a round trip. A recording apparatus will be set up in Paris which will be capable of revolving at a speed of from 1,000 to 5,000 revolutions | per second. A wireless flash sent by the Paris station will be heard in Washington, and, if possible, will be automatically flashed back again, thus automatically flashed back again, thus automatically resistering on the revolving drum in the Paris observatory. This test will not take place until after the longitude tests have been com-

There is considerable doubt as to whether the method will be practicable, for at present there has been no invention which would permit the "flash back" to the sending station without some degree of personal error.

## The Current Supplement

A N article in this week's SUPPLEMENT AO not be design and use of scientific instruments in acconautics will be found to state fundamental principles of design applicable also in other fields.—A masterly model of Rome at the time of Constantine is illustrated and described.—F. #### The Truth About the Iceberg Peril

HAT famous craft, the United States revenue cutter "Seneca," Capt. E. E. Johnson, has added e more to the long list of the valuable se a) ole more to the long list of the validate services which she has rendered to navigation. The "Senseau" it will be remembered was detailed to petrol the fee field during the spring of the present year, looste the position and course of the lesbergs, and make a thorough atroly of this peril and the best means to detect and a vold it. The report of Capt. Johnson shows have well the work was done.

All of the ice seen on or near the Grand Banks this season has been in berg form. The largest berg sighted measured 400 feet long by 300 feet wide and it stood 70 feet high out of the water. All were white in color and no two bore any striking resemblance to each other. The "Seneca" sighted every type and shape of toeberg except the kind popularly pictured in school books, with high, overhanging, craggy pinnacles. The Captain sighted no bergs of the enormous size reported in the newspapers, such as were stated to be half a mile long and 300 feet high. The loftiest berg that he saw was estimated to extend only 150 feet above

The greatest distance at which ice was observed in clear weather by day was eighteen miles. nevent wender by any was eighteen miles. The average beer, on nordinarily clear day, can be sighted from 13 to 16 miles from the ship; on a cloudy day, from 11 to 14 miles. In a slight fog berge can be sighted at 2 miles, in a dense fog at 200 yards, and in drizning rain at 2½ miles. In bright monlight they can be seen at 2½ miles with the raised was in strain. can be seen at 24 miles with the naked eye; in star-light at 1 mile, and at 2 miles distance with glasses. On a night overcast and dark, but with the horizon bergs can be seen at a distance of one half mile with glasses

With a searchlight a berg can be seen at 3 miles on a dimly moonlit night, and at 2 miles after the moon has set; but the observer must stand 15 feet away to one side of the beam if he would see readily. Capt Johnson states that with the beam turned on a berg abreast the ship and 2 miles away, he could see it as plainly as an illuminated store front from the quarterdeck when he was standing about 100 feet from the light. It should be noted that the beam must be drawn to a fine focus, and that a flaring beam blinds the observer. Because of its blinding effect, the Cap the observer. Because of its binning curet, into aspiration would not recommend the general use of the searchight for a vessel under way. Very pertinent is his remark "On a dark night or in thick weather, the vessel in the vicinity of bergs should slow down so as to be able to maneuver within the limits of visibility."

Important, also, is the fact that about ninety per cent of the attempts of the "Seneca" to locate an Iceberg by means of echoes gave no results. The existence of an scho indicates the presence of a berg; its absence proves nothing. Usually an echo will be obtained only found that in a light, low-lying for, the observer could see a berg from aloft sooner than from the deck; on the other hand, in a dense fog it was found that the

lookout was most effective when it was kept from the loucout was most enective when it was super tron ine spar deck, as the first sight of the berg was the ispping of the water at its base. It was noted that the roar of breakers on a berg and the rembing of breaking ice could be heard as far as a malle distant oil a calm

#### Multi-gun Turrets

F the question of how many guns it is best to mount in a single turret were left to the decision of the gun-pointer, the man who elevates and fires the gun, he would unbesitatingly pronounce in favor of one gun for each turret. In a single-gun turret the one gun for each turrer. In a single-gun turrer the gun is mounted directly above the vertical axis of the turret and the shock of discharge does not tend to rotate the turret to right or left and throw the gun off the target. In a two-gun turret, the axis of each gun is several feet from the vertical axis of the turntable on which the turret rotates. Conseq energy of discharge constitutes a powerful moment, tending to rotate the turret—the discharge of the gun to the right of the vertical axis of the turret swinging the gun of the vertices axis of the terret awanging the gun of to the right, and vice verse. It is attempted to resist this tendency by powerful friction clutches; but they are not fully effective and the discharge of me gun is liable to throw its fellow from one to three degrees off the mark. This requires re-sighting and involves delay.

It was the saving of weight both in armor and oper It was the saving or weight both in armor and operating goar that led to placing two guns in a turret; and for many years past this has been the standard practice. It is largely the same consideration that led our navy and those of Italy, Russia and Austria to adopt the three-gun turret. Another compelling motive, which perhaps more than any other is answerable for the introduction of the three-gun turret, is the fact that it simplifies the work of the gun-pointer, by concentrating the splash and enabling him to make a more acnate of the errors in range and traverse Similar considerations have now led the French naval architects and ordinate officers to go one step further and place no less than four guns in a single turrer; and their latest sbips, the "Normandie," "Flanders," "Languedoc," and "Gascogue," are committed to this arrangement. Just how great is the saving of weight due to this concentration may be judged from the fact that these ships are to carry twelve 13.4-inch guns and twenty 5.5-inch guns on a displacement of only 25,000 tons Our own "Pennsylvania," which will mount a tons Our own "Bennsylvania," which will mount a battery of approximately the same weight, rie, twelve 14-inch guns and twenty 5-inch guns, is of over 0,000 tons greater displacement; and although the larger part of this increase is due to the greater size of the ship and the heavier armor, it is certain that the elim-ination of one turret (the "Pennsylvania" carries it main battery in four turrets) with its beavy barbeite, operating gear and other structural weigh count for a considerable amount of the difference.

A serious objection to multi-gun turrets which has A section objection to mutricipu turrets when has been developed at the proving ground tests, has been the fact that the powder blast of the guns tends to throw the shells out of their true path and produces objectionable dispersion. The powder gases, as they burst forth when the base of the shell is clear of the ourst torm when the case of the shell is clear or the music, still carry a pressure that is exceedingly high—between seven and eight tons; and this blast, impinging on the abells of the adjoining guns, somewhat disturbs the accuracy of their flight. The difficulty can tures the accuracy of rear might. The dimensity can be met in two ways: first, by thinking the discharge so that each gun is a small fraction of a second behind the adjoining gun, each shell getting sufficiently clear of the blast of the adjoining gun to be free from inter-ference—a method which is open to the objection of displacement of the turret, attendy referred to above; secondly, by inlacing between the muscles shelded of condly, by placing between the muzzles shields of sufficient strength to oppose the lateral dispersion of the gases until the shells are well clear of the sone of interference. If the weights involved are not prohibitive, this would be the better plan. There can be no doubt that the French navy have given to this problem the most careful investigation and are well satisfied as to its efficiency. But it is a bold step; and the inno-vation will be watched with great interest throughout the navies of the world.

#### Renaissance of the Bicycle

ECENT statistics presented by the Cycle and Automobile Manufacturers' Association of France suggest that some day there may be a renessance of the interest and use of the higyele in this country. According to the reports of the Association for 1912, there were in France at the close of that year S0,155 motor cars, 95,641 motor eyeles, and 2,009, 985 bicycles. With the exception perhaps of those who are directly interested in the bicycle infustry, in this country. Americans will be astonized to higher that in a single country of Europe there are nearly 3,000,000 bicycles in use, and that one person in every thin owns such a machine.

To those of us who sade the t years ago—and who did not opinion that the company of the company ers ago

AND THE SAME REPORTED BY THE SAME REPORTED BY

maintain a thriving industry, particularly in the image; facturing centers and in such trural emission as any facturing centers and must visit Europa to appreciate the fact that, there, the bicycle has not only held the own, fact that, there, the bicycle has not only held the own, but is increasing in popularity and usertusess. Most surprising will be the degree to which the cycle is used in the very heart of the most populates claim. Strong and serviceable machines, with a complete equipment of multy service on the most crowded shreak, and are used by a wide variety of people in their failty, work. The trademan, delivery boy and messenger, predeminate; one also sees mounted postnen, soldiers and even policemen; not the policemen of a messured estres. policemen; not the policeman of a meaning corps, as we have them in this city, but policemen who are eviwe have them in this cut, our possession was see see dentity using the machine to get to and from their vari-ous bests. Surprising and very interesting are the fear-lessness and skill with which the bisyclist pinnges into the thick of the complicated traffic to European capitals, and accidents seem to be comparatively rars. No doubt this is due in a large measure to the spirit of respect with which the bicyclists are regarded by the beavier forms of traffic. Furthermore, American will be interested to learn that the bicycle is still extensively used in Europe as a means of pleasure. Thousands of people make use of the machine for touring. and so obtain in a chesp, healthy and most enjoyable way, that initmate knowledge of the scenic beauties of the old world which a bicycle tour makes possible. As showing that there has been no such abandonposet of the bicycle in France as has occurred with us, and

that its present popularity is not ephemeral, it may be mentioned that ten years ago there was but one bleycle in France to every thirty persons as against one for every thirteen to-day.

The New Chief of the Weather Burn A FTER an interregum of more than dases among a month, following the summity nearest of the United States Weather Bureau, an admirable accessor has been appointed in the person of Prof. Chartes Prediction that the Arvin. This appointment puts and to a situation that has caused some connormance and to a situation that has caused some connormance. American meteorologists and other persons interested in the future of official meteorology in this country. It the future of official meteorology in this country. It was understood from the outset that this position would be filled on the basis of scientific merit, without refree ence to politics, and that the President had sought the advice of the National Academy of Sciences before undertaking to make a selection; also that fire Academy of Marie and Academy of Sciences before early had appointed a committee which had several names under consideration. However, in contrast to these supplicious arrangements, rumor successively the several present such as the several present whose whose several present when the several present sever immee under consideration. Inverses, is consense to these auspicious arrangements, rumor successively named as the probable appointes several persons whose qualifications for the post were by no means obvious. Apparently meteorological attainments were to be the

apparently meteorological attainments were to be the least influential consideration in filling the most import-ant meteorological post under the Government!

Happily the danger of a mikel apportization has been averted. Prof. Marvin has been connected with the mattonal metacological service for nearly thirty years, having entered the service as a junior professor in 1884. having setered the service as a junior professor in 1884. He is known all over the world as an inventor of metacological apparatus, and has been a roluminous writer on the recipical as well as the practical side of instrumental intelectology. In recent years he has devoted special attention to improving the ensteoregraphs used in connection with kites and ballooiss for exploring the upper air; to perfecting hygowestic apparatus and methods; to the calibration-of amenometers to the measurement of evaporation; and to the improvement of pyrheliometers. Prof. Marvin is a very hard worker—a man of singular modesty and appacational contents of the weather Bureau and the justile if meryes are to be congratulated.

The state of the s

#### Electricity

Maiuring Cheese Electrically.—A British trade paper reports that an electrician of Rotterdam has discovered a method of maturing cheese by electricity. The method consists in subjecting fresh cheese to an alternating current for 24 hours, which treatment results in giving to e all the properties hitherto acquired by aging.

Cost of Lighting Motor Cara,—In order to determine just how much power is used by electric lighting systems of actomobiles, tests were recently conducted at the Indianapolis Motor Speedway. Standard cars were used in the test and they were run as far as possible on a single gallon of gasoline with the electric generating apparatus disconnected. The same car was then run as far as it would go on a gallon of gasoline with the g rating appearatus connected, and the difference in distance traveled showed what proportion of the fuel was consumed in driving the generator. It was found that for higher power cars the fuel consumption for the electric system amounted to 7.3 per cent and for the lower cars 10.77 per cent.

New Method of Sealing Conductors in Glass .- Writing New Method of Sealing Conductors in Glass.—Writing in the Electrical (London) George B. Burnaide describes a new method of hermicially sealing electrical conductors and through glass and other vitroous plass and other vitroous distances. An aperturn is formed in the glass, just large enough to receive the conductor, and after the conductor has been innarted the glass is strongly heated by means of a blow-pipe flame, until perfect consistent has been obtained between the glass and the conductor. The seal is them the conductor of the flames are desait for each of the flames are desaits for each of the flames are desaits for each of the flames are desaits flames and the flames are desaits for each of the flames are desaits flames and the flames are desaits flames and the flames are desaits flames and the flames are desaits flames and the flames are desaits flames and the flames are desaits flames ar of the fiame and when it reaches a dull red heat it is cooled by several immersions in a bath that may consist of by several integerations in a bath that may consist of sperin, or other oil, wax or fat, previously warmed. Each immersion should hast about two or three seconds until the seal is completely cooled. In this way local differences of tempersture are avoided and hence there is no crashing of the giass exound sple conductor. If a large conductor should be used it should preferably be sealed in place in the form of a tube which may subsequently be filled with a conducting substance.

Blectrifying German Railreads.-As a result of tests made on a 15-mile section of the Magdeburg-Halie Railroad, the administrations of Bavaris, Baden and Prussis have decided to use the high-tension single-Prussia have decided to use the high-tension single-phase system, employing also a low frequency. In the test the electric locomotives covered as much as 25,000 miles and showed a very good performance, as that it has now been decided to use the same system in the proposed scheme for the suburbs of Berlin, cover-ing no less than 250 miles of double track and cesting 890,000,000. From another source we learn that elec-tric truction will probably be adopted on the Magde-burg-Leipzig section, which is about 100 miles long, and another extensive provisor palese to the Jackson. and another extensive project relates to the Lauban-Königszelt line in Bilesia, covering 80 miles of direct line and 90 miles of branch roads.

Resistance of Tungsten at High Temperatures. -courate measurements on the electric resistance of Accurate Messagrammers on the electric resistance or tungetes at high temperatures are made by Pirali, and he uses a strip of this metal 2.4 inches long, 0.05 inch wide and 0.002 inch thok, mounted in an exhausted bulb. The strip is soldered to a pair of very fine wires as a support so as to have the heat radiation uniform as a support so as to have the heat radiation uniform, such as in not the case where the filament is attached to the support of an ordinary lamp, for the support carries away heat from the ends of the filament and makes those cooler than the remaindor. He takes the temperature of the tungerien strip by using a Holborn pyrometer, and finds that the ratio of the resistance cont. (taken as unity) is 7 for 1,200 deg. Cent., 10 for 1,000 and 12 for 1,900 deg. Cent.

A Curious Electric Plant is used in connection the old hydraulic plant on the Seme known as the "Mariy machine." The original water wheel and pump plant was put in at the time when Louis XIV built the chateau of Versailles, in order to elevate the water the chalcas of Versailles, in order to elevate the water meeded for the numerour basins and fountains, but it was remodeled in 1856 by the use of more modern water wheels and machines, employing 40-foot under-shot wheels, five in number. But so part of the water had to be used for the city drinking supply of Versailles, the Seins was employed only for power and purer water was pought in a number of large wells much in the vicinity was sought in a number of large wells ann't in the vicinity within recent times. Portable engine groups were installed at the mouth of the various wells in order to raise the water to the uniface previous to sending it to the main pumps. However, within a recent period the engineers found that the Seine Itself could be called upon to furnish the powing for this purpose as well, so that in an adjoining building there were installed not 100 here-power buffuses fed by Seine water, and each tarthine drives a \$5,000-volt alternator. This ourself goes over lines to \$60 hoves-power motors at the well mouths for driving the pumps, so that the steam eagines are only needed or assecondons when freshots in the Seine lower the fixed of water and prevent the numbles from running.

#### Science

A New Honor for Wassermann,-Prof. von Wass mann has been appointed superintendent of the new Kaiser Wilhelm Society for Experimental Therapy at Dahlam, which was founded by the Kaiser Wilhelm society for scientific research

Memerials to Schlaparelli.—A committee comprising the heads of leading Italian scientific institutions and presided over by the King of Italy has been formed to obtain funds by pubble subscription for paying suitable honor to the memory of the late Prof. Guyanni Schin. parelli, the distinguished astronomer. It is to erect a monument to him at his birthpla It is proposed gliano, in Piedmont, and to place a memorial tablet in the Brera Palace at Milan. He was connected with the Deers Phases at Minan. The was connected while the Observatory of Brees for forty years, most of that time as director. To the world at large Schiaparelli was chiefly famous for his discovery of the so-called canals" of Mars in 1877.

The Study of Mountain Snowfall .- Our attention has been called to the fact that a note on "The Economics of Mountain Snowfall," published in our Science Notes column of January 11th, 1913, was somewhat ambiguously worded, with the result that credit appeared to be given to the Weather Bureau for discoveries conhe given to the Weather Bureau for unscovered con-cerning the relation of certain types of forest cover to the conservation of snow on mountains. As a matter of fact, we are not aware that the Weather Bureau lays claim to any such discoveries. The pre-eminent lays claim to any such discoveries. The pre-eminent worker in this field is Prof. J E. Church, Jr. of the University of Nevada, and it was the results attained by him that we summarized in the pertinent portion of our note

A German Observatory in the Far East.—The Impereal Observatory at Tsingtau, capital of the German colony of Kiacchau, China, is rapidly becoming one of the leading scientific institutions of the Far East. the meaning scientific institutions of the rar rest.

Originally founded chiefly for nautical purposes, it now carries on regular work in terrestrial magnetism, seismology, astronomy (including time-service), tidal observations, adjustment of compasses, chronometers, etc., and, above all, practical meteorology. The observatory receives telegraphic weather reports (parily by wireless) from a large number of stations in China, Japan, Korea, and Siberia; also wireless weather : ports from all German war vessels on the Asiatio station Daily weather mans are published forecasts ports from an electron was ressent on the Amatic station Daily weather maps are published, forecasts issued, and storm warnings displayed. When a ty-phoon is reported on the adjacent seas the observatory keeps in constant communication, day and night, by wireless with German men-of-war, and is thus enabled to follow the progress of the disturbance with gree

The Chinese Wood-oil Tree is the subject of a circular by David Fairchild recently published by the U. S. Bureau of Plant Industry, the purpose of the publication being to advocate an extensive cultivation publication being to advocate an extensive cultivation of the tree in this country, where it has been grown in a small way since 1906. The importance of this recommendation is shown by the fact that the millions of wood oil (also known as tung oil), made from the seeds of this plant was imported from China hat year, and the product is said to have had a revolutionary offoot on the variois industry of the United States. It has, asys Mr Farichild, largely taken the place of kauri gum and has made possible the manufacture of a quicker driving variois, wheth is less than the control of the place of t place of Kauri gum and has made possible the manu-facture of a quicker drying varnish, which is less liable to erack than that made from kauri gum, and has been found of special value in waterproof priming for cement. The tree is elimatically adapted for cul-tivation in the Southern States, and the Department Agriculture is distributing one-year-old specimens ona fide experimenters.

Dr. Babcock's Retirement.—Dr Stephen M Babock, for twenty-five years professor of agricultural hemistry at the University of Wisconsin, and the invencasematry at the conversacy or wisconsain, and the inven-tor of the famous milk test which revolutionized dairy methods twelve years ago, has retired from active work with the appointment as Professor Emeritus of the uni-versity. The milk test, which is a method for the ac-ourate determination of fat in milk, is not Dr. Baleccek's only invention. Among his other donations to science are a viscometer for testing the viscosity of oils, a gravimeter for analyzing milk and a method of chloroforming milk to produce a ferment, called galactase, which is used to ripen cheese. As the result of one of his investimilk to produce a terment, called gazactase, when is used to ripen chosee As the result of one of his investigations he discovered that the liquids produced by living plants and saimals are not wholly waste producted but subserve a useful purpose through which, for example, the ascent of sap in trees and the usceulence of fruits is explained. Another of his investigations led to the explained. Another of his investigations led to the deduction that "the weight of a body is an Inverse function of its inherent energy." Declaring that the results of his work belonged to the State which he was serving and not to himself or to any other individual. Dr. Babcock has always refused to take out a patent on any of his inventions. Many of his discoveries have proved of

### Another Contest for the "America's" Cup

#### The Return to Yachts of Moderate Dimensions and Wholesome Type

THE New York Yacht Club has recently announced that the Royal Ulster Yacht Club has signed the conditions for a match for the "Americas" cup, and that the first race will be sailed Thursday, September 10th; the scool, September 12th; the third Reptember 14th; other races which may prove to be necessary to be sailed on each following Thursday, Saturday and Tuesday. Thus this famous trophy, the best known and most valued yachting prize in the labstory of receiving the content of the scool of the New York Yacht Club, is until to be made the object of a memorable contest.

During the past three decades there have been eight series of races for the cup all of which have defending yacht The races were as follows: "Genesta"— "Purltan," 1885; "Galatea"— "Mayflower," 1886; "Thistie"— "Volunteer." 1887 "Valkyrle I l."-"Vigilant." 1893; "Valkyrle III" "Defender." 1805: "Shamrock I."— "Columbia," 1899; "Shamrock 11"— "Columbia," 1901; "Shemrock III." -"Reliance." 1903

In these races the time allow ance which the larger yachta gave determined on the terline length nd sail area Each designer a waterline length not to exceed 90 feet So long as he kept within this length. he was at liberty as broad and as deep as h pleased, and pread above her hull as great an eres of canvas as he thought During these thirpetition, the operatlon of this rule produced a very extreme type of boat, with great beam and length on deck, of ex-treme draught,

treme dramph.

and carrying un enormous sall spread, requiring a very large errow for its handling. The effort to carry the ingrest possible sail spread showed theely both in the form of the hull and the materials for construction of both hull and spars. The extreme form of yacht produced is well illustrated by the 'Reliance,' which, on a waterline length of 80 feet 8 Inches, had an overall length on deck of about 145 feet, a beam of 27 feet, and a draught of about 20 feet. In cross-section, the hull presented the appearance of a shallow well out into the bow and stem section, with a flat floor and hard bliges. The hard bliges were carried well out into the bow and stem sections, with a flat floor and hard bliges. The hard bliges with a flat floor and hard bliges. The hard bliges with a flat floor and hard bliges. The hard bliges with a flat floor and hard bliges. The bard bliges with a flat floor and hard bliges. The bard bliges with a flat show when the special held, she immersed a longer waterline, the original 80 feet new sections, with the result that when the vascel heeled, she immersed a longer waterline, the draming and thin Toblishrance sheets for the platting enabled the designer to reduce the hull welfars and proportionately increase the mass of lead welfars and proportionately increase the mass of lead

at the bottom of the keel. A further increase of the lead ballast was made possible by the substitution of hollow steel masts and spars for those of solid wood. Such construction enabled Herveshoft to place about 85 tons of lead in the keel of the "Reliance" and to spread above her hull the enormous area of 18,247

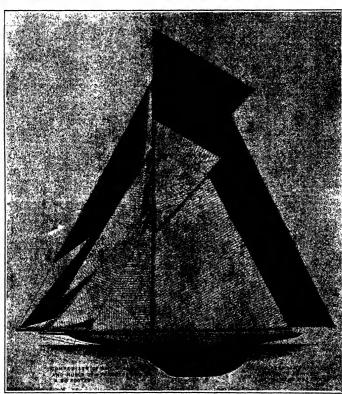

Now such a hilp as the "Reliance" not only costs about \$150,000 to build, but her running expenses are proportionately heavy. She requires a crew of fifty or more men effectively to handle her; she is an uncomfortable boat in a seway; and after a series of ieagth-and-sail-area rule had got in 'its pressistives work of producing freakish beats of somewoods sail area, a boat of 85 to 90 feet waterline carried a sail speeds of from 9,000 to 11,000 equate feet, and such does were reasonable in price and, in cost of management, and were readily handled. When his satispayanted dimensions of the "Reidance" were reached, the cost, and trouble of building and managing these yackts became vary serious indeed. A return to yachts of smaller dimensions, such as contended for the cuty in the seventies and sixties, became desirable. The British chair-lenge sent by Sir Thomas Lipton through the Royal

Ulster Yacht Ch gave the length modern vachi carries a sail area approximately equal to that of the 85 to 90-foot yacht of 20 years before; and she is sufficiently large to provide a thorough test alike of the skill of the designer, the build-er, and the competing skippe and crews. and crews. At cost of construction is cut in balf. of operation Moreover, under yacht is built which after the be cross-bulkbeaded and turned into a fast and thoroughly ser-viceable cruiser.

The accompany superposed drawing of a typical modern 75-foot racing yacht and of the "Reliance" shows at a glance what an all-round reand increase in cured by a reducthe waterline length. As com-"Relience" over-all length on deck is reduced from about 145 to 105 feet, the beam the draught from 20 feet to 18 feet 9 inches, and the

lead that must be molded into the keed to give stability is reduced from 95 to about 37 tons. The main boom is reduced from 115 feet to 84 feet and the height from boom to topmast drops from 135 feet to 111 feet. The cost fails from \$150,000 to \$80,000, and the cost of running the two types is as two to one.

As to the prospects of our retarting the cup in this country. It must be affinited that the reduction in the country. It must be affinited that the reduction in the country. It must be affinited that the reduction in the country. It must be affinited to the country of the cou

The larger yacht is the "Reliance," the last cup defender; the smaller is a typical 75-foot racer.

Comparison of a 75-foot with a 90-foot racing yacht.

races is over, she is useless for ordinary cruising. The fate of a yacht of this character is usually that he is broken up and sold for the value of her media. During the past few years American yacht clubs have dopted a new rule of measurement, which has produced a type of yacht that is practically as fast as the older type, and which has the advantage that her hull is deeper, more commodious and better suited for cruising. The old rule of waterline length and sail area produced a boat of very small displacement in comparison to the great spread of sail—a most undestrable combination. The new rule favors displacement and groduces a boat with a deeper and fuller unsferwater body, and sharp ends, as against the full overhanging ends of the older type.

The contending yachts bulk for the last four periods.

. The contending yachts built for the last four series of races have been of approximately 90-foot waterline length, and in the preceding four series of races the waterline length was about 85 feet. Now before the

CONTRACTOR STATE

#### A New Baseball Indicator By Guy E. Mitchell

WHEN the World's Series is played in October between the two championship teams of the National and American leagues, the fans of the two winning cities as well as in the other cities of the leagues

Electrically lighted incubator thermometer.

the base lines, side, run after fly balls, hold consultations on the field and quarrel with the umpire to hide their own short-comings.

The diamond with seenery is fairly large, and occupies the full depth and width of a theater stage. In the front are shown devices so that the spectators may keep track of the outs, balls, strikes, runs for the inning,

errors, fly halls and in certain plays, whether the runner is out or gafe. On either side is the "box score" luclined to the rear is the diamond proper with two grooves encirching it. In one of these the players move, while in the other the runners move from base to buse.

The manikins that enact the plays are themselves about a foot and a half high, but the working mechanism, which is not seen by the spectators, is just as long. This consists of a dry elec

sits of a dry electric cell from which current is carried to a small half candle-power electric lamy. In the hand of the fluxre-Then through a system of levers the operator is able to raise either right or left arm or both, or cause the fluxre to bend over. In running bases the wheel altached to the manifin fits the lease-runner groce, and in revolving causes the legs to move backward and forward. If the operator whiles to make the fluxre silde into a base it is necessary only to incline the entire device in the direction desired.

Electric cake-making machine of three

Besides an electrician who operates a switchboard from which hits, files, and the devices in front are shown, nine men are required to handle the players. One of these men also announces balls and strikes as

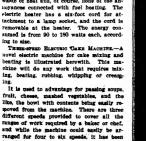

the plays are made. At the commencement of the game he calls "play ball." The nine fielding players in their white suits come up through holes in the diamond and take their respective positions, and the batter in his brown suit comes up through a hole near the home plate and with bat in hand takes up his place A light appears in the pitcher's hand—if he is right-handed, in his right hand, and if left-handed, in his left hand. 'winding un" he delivers the halls toward the batter. The light in his hand is extinguished, and if the pitcher is inclined to be wild it is shown in the catcher's hand. the umpire raises his left arm and the am-nouncer calls "ball one". If the batter makes If the batter makes a safe hit--say for two bases to left field --the progress of the ball is shown on the ground from home plate, between shartstop and third base out into left, where the fielder stoops and the light is shown in his hand. He throws to third base, who in turn relays the ball to the pitcher Possibly the batter was forced to slide into second, but that play is faithfully presented. If, however, the batter merely hit a fly to left field, a light glows over the shortstop's head, then over the head of the left fielder and then in his hund When the side is out, the manikins in white go down through holes and off the field and their places are taken by maniklus in brown, while the batsmen are dressed in white lf. e, a pitcher is being hit very hard and is taken out of the box, that fact is faithfully presented by a consultation be-tween the captain of the tenm and his pitcher and the exit of the latter through a hole near his position in the center of the diamond. If the outgoing pitcher be right handed and his successor left-handed the difference in delivery is faithfully portrayed as is also the usual position occupied by the batters

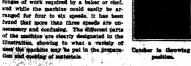

Great entitudence is around among the fans who witness a game on the hourd. Or they see a ministure player representing their playing fold strike out hatter after batter, or the team's slugger lift the hall to all corners of the field with the fielders in pursuit, or mayir the speedy base-namer stealing bases and adding beyond the reach of

will be able to witness every move and every act of the star players through a device which was patented last February by Thomas H. Jackson of Seranton, Pa., and which has been in operation for the past two or three months at Atlantic City, Washington, D. C., Rochester, N. X., and at Mr. Jackson's bome. This 'player' is unlike many of the contrivances heretofore shown, where both players and the bell have been represented by electric lights or colored glass with lights behind them, but is a faitful representation of the game—diamond, grandstand, fences with advertisements on them, the prise winning bull, the scoreboard in center field, and lastly, unpire and players that do everything bull talk. These players throw and catch the ball, run

In the play shown the batter has hit to the second baseman, who threws to third base in order to catch a sliding runner.

Catcher in catching passition.

the basemen with all the realism of the game. Once the operators become expert there is no play made on the dlamond that cannot be reproduced on the device and shown without the need of explanation.

#### A French Cycle Racing-car By S. P. McMinn

THE grotesque-looking little car that appears on our front range this week is the French "Bedsia," that was illustrated and described in the Sacciary of Bedsia and the was illustrated and described in the Scientific American some weeks ago it is of the same sort, but this particular one was developed primarily for speed, and its makers held strong hopes that ill would win the Grand Prix race for cycle-cars, as these little vehicles are styled, which was run off near Ambans on July 12th; but it only succeeded in getting second place despite its elimeter preparation. Notice the narrow tread and the way the driver and his mechanician are seated one lichild the other to reduce wind resistance to the minimum, the disked wheels, and the peculiar meaner

in which the front axie is braced.

Structurally the car is a little bit different from
its predecessors of the same name, and in its makeup there are a number of very luteresting fe The engine, for instance, is a twin-cylinder air-cooled machine with the cylinders set at 90 degrees to each other and a bore and stroke of 82 and 100 millimeters. respectively. The motor is mounted on rails so that it may be moved fore and aft a certain distance in it may be moved rore and art a certain distance in order that the driver may loosen or tighten the belts through which the car is driven; this movement of the engine is controlled by a worm gear operated by the driver. There is no clutch, properly speaking, not is there any countershuft, the drive from the engine being taken directly to the rear wheels through two long belts about twelve feet in length. The driving pulleys are mounted directly on the ends of the engine crankshaft and are of a very unusual type. In the hirger part of them there are small centrifugal govern ors, and as the speed of the car advances, these con irivances draw the cheeks of the driving pulleys to gether slightly, thus increasing the diameter of the driving pulleys and thereby amplifying the genr ratio between the engine and the road wheels. As the speed of the vehicle drops off, the pulleys spread and the gear ratio sutomatically is lowered; thus it is practicully impossible for the operator to "stall" his motor, for gear changes are taken largely out of his hands He can, of course, shift the engine and permit the belts to silp, and in this way obtain a very low goar ratio, but a very inefficient one withal No differential is nsed, quite as a matter of course, for in rounding curves one of the belts slips slightly, thus compensating for the difference in speed of the driving wheels Throughout the whole of the construction the alm of the designer has been to obtain the very lightest weight consistent with strength, and to this end the frame is drilled out wherever possible. Steering is done by means of steel cables wound around a bobbin much after the manner of the typical marine steering gear. Two cables are used, one heavy and one light, and both are passed through fiber tubes where there is any likelihood of chafing. If the heavy cable, which is the one normally in use, should be broken through accident, the lighter one then comes into play, virtu-

#### Millions for Naval Armor—the Remedy By Louis E. Browne

ally, it is nothing more than an emergency rig

A RMOR plate for modern dreadnoughts costs the AT United States one third of the whole amount appropriated for the construction of the vessel. It is the most expensive factor which goes into the make-time of the might phase the state of 10 just three plants in this country. Armor costs the Government \$551 per ton, and the required 10,000 tons needed for one ship or the 20,000 tons needed for one ship or the 20,000 tons needed for one ship or the 20,000 tons needed for one ship of the sound of the state of the ship placed in commission, resulting in an approximate cost to the nation of \$4,540,000 for each ship placed in commission.

placed in commission.

Josephus Duniels, Secreticy of the Navy, has deterulted upon a policy looking to the ultimate establishment of a unval armor plant to a letter to Congress
be said that If Congress authorized a plant large
counsit to produce 10,000 tons per year, or half enough
for a two-battleship programme, the cost of the plant
would be shout \$8,400,000 and the saving in the cost
of armor plate would be about \$140 per ton on the
price of \$450 now paid. Thus, according to his estimates the United States would save \$1,400,000 on 10,000
tons of armor or the carties or or the control or the

tons of armor or the yearly output.

The naval service is divided in opinion as to the advisability of the Government plant Mr. Daniels frankly stated that many problems must be solved before the wisdom of such a plant could be reached, and this at the property operators for the state of the state of the such as the

that at present no accurate figures are available.

Because of the expensive machinery, the Secretary

of the Navy, in a letter to Congress, says that the armor plate industry is susceptible to monopoly. Investigation shows that foreign governments pay their armor plate manufacturers a higher price for armor than does the United States. Three governments in Europe have established national armor plate factories with the result of great saving. They are France, Russia, and Italy. Engiand and Japan are contemplating governmental ulants.

All armor for the Nevy is to-day saids in the Cannegic, Midwise and Rethishem plants at juestically formed to the control of the work is coming to them without reference to the price they bid, have usually submitted bids nearly identical. In the past thay have received one third the work suyway, whether high or low hidders. If one bids much lower than the rest, the other two companies have been awarded their share at the figure of the lowest bidder. The Scertary of the Navy makes these assertions upon the authority of letters received from the Midwale Steal Company and the Betthelmen Steel Company.

Special machinery of extremely costly nature is required to manufacture armor plate more than 1½ inches in thickness. The three named companies are practically the only ones in this country having the

practically the only ones in this country maying the necessary machinery.

Since John Stevens of Hoboken, N. J., proposed armor for war vessels in 1812, the art has advanced to the present high state of perfection.

The object of the modern land-faced super-carboniced armor is a metal homogeneously hardneed as hardness if not harder than, the projectile, and at the same time so tough as not to be shattered by the terrific impact. This armor comprises a series of operations which require the greatest care and attendion to detail, and neatily after receiving the drawings, nine months are required to turn out the finished article. Fourteen operations are received article, the composition of the contracting the low-

Fourteen operations are necessary—custing the low-carbon ingot, stripping the ingot, removing the scale, rough-mechining, carbonizing, scaling, reforging, an osciling, mechining, bending, tempering, rectifying and finish-machlining, and respecting. Tests are required arter forging and tempering. The ingot is placed in a 50-inch double forging press, and willie at red heat subjected to a hydraulic pressure of about 14,000 tons. Then the plate is carbonized. This is an adaptation of the long known process of cementation, which means heating the metal to a high degree of heat in the presence of earbon until the carbon is gradually absorbed into the surface. In bending great care must be exercised, and none but the most skilled artisans operate the huge bending presses, which exert a pressure of 7,000 tons on the plate.

The plate is then heated and sprayed with cold water, at a pressure of 25 pounds to the aquare inch. The plate usually warps and becomes distorted under the plate usually warps and becomes distorted under the treatment, and even under the most akilled it treatment that plates usually have to be rectified. In the Krupp armor characteristic reads, sometimes one quarror armor characteristic reads, sometimes one quarror as inch wide, aspear, but under the Harvey process smoother believes are produced.

smoother joines are produced. It is the final machining and rectifying that cooks so much money. Besides being bored and smoothed, the armor has to be fitted to seach piece which goes into the armor bett and urrets of a ship. It is like a jig-saw puzsit. Little grooves here and there, a notch in one end and an over-lap in the other, and finally the determination of the accurate consiers of the holes for the armor boils, require the constant attention of haif a doesn skilled men for all or eight weeks on each piece

The Secretary of the Navy has faithfully studied the armor problem and is about ready to submit to Congress some definite tiles of the actent of the plant. He holds that with a national armor plant, the Government could determine the accurate cost of armor and then, knowing the oast, require the private concerns canbmit black allowing them a fair profit on the work. Mr. Danfels has submitted a few general facts to Congress regarding the purchase of armor plate by the Government. The actual cost of armor for war vessles of this nation aface its introduction is 187,106,482, of which \$30,844,153 was paid to the Carnegle Steel Company, \$415,151,12 to the Bethishem Steel Company, and \$12,044,217 to the Midwale Steel Company, and \$12,044,217 to the Midwale Steel Company, and since the fairly of the companies for the fairly of the product to foreign autions to foreign autions.

Should Congress authorize the plant, it will be located in Washington near the naval gan factory. Three-separate buildings would be needed to accommodate the special machinery. It is the present fides, if the plant is established and proves a success, to later established and proves a success, to later establish a similar plant of the same capacity on the Pacific coast. This would put the Government in a position to manufacture all of its armore. These, has been a protest against taking the work away from the civilian plants on the grounds that their capacity would be

#### The Electrical Control Boards for the Pamaun Canal Locks

THE great game of the looks at Gattin and Mirraflores of the Parisma Canal will be electrically
operated. The control boards, which have been especially designed and built for this purpose, are now on
their way from Scheueckady to the Canal Zona. In a
future issue of the Scheuertzki Alexancan we hope
tyo an extensive lithustrated description of their construction and operation. Suffect to say for the present, that each board is an electrical counterpart in
miniature of the lock which it controls. By a readingusulous system of lights and scales the operator can
see exactly what is the height of the water in any
particular lock and can watch its gradual stall. The
boards do not control the lock gates directly, but rather
the motors which swing the gates. Readers of the
Schravitz Amazican will recall that the lock chambers
are 1,000 feet long. Many of the vessels which will use
the canal are smaller than this, for which reason provision has been made to divide the chambers into lesser
parts for small vessels. This sub-division is electrically
effected from the control bandes must be operated in a certial order, automatic locking devices having been provided to prevent their operation in any but the correct manner.

#### ir Elizan Maxim Asks a Question

To the distor of the Scrawerzo Assumcan:
Asserting to Lowell and some other astronomers,
there was a time when this Held seath of ours was
being boiled at a semprestire of 212 day. Fahr.
Of corres, this is quite true, but it would be at
a time when presidently all of the water was on
the spirit instead of in the atmosphere.
I signed the to sake the opinion of some of the
selection must of America as to what was the
highest temperature during this boiling process,
that is, when the safface of the earth was so very
hot than you water remained on it,

highest's temperature curring the coloning process, that is, when the carriage of the earth was so very hot that very little or no water remained on it, practically all of the water being in aqueous vapors mixed with the atmesphere; then, agaid, it is quite-possible; that the quantity of carbonin said gas—was very great at that time.

Some geologies have told us that about three queriers of the total weight of the earth is made up of timestens. If such be the case, and before any estimate acid gas was absorbed to form limestone or was transformed into coad, there must have been a very heavy pressure on the surface of the earth, perhaps a pressure so great that the first water that remained as liquid would be resting on a red hot curface.

If such he the case, it is very evident that we were being very severely boiled at one time, and at, a still later date the downpour of het rain must have been very great indeed. This state of things must have been very great indeed. This state of things must have continued for many thousands of years.

at, a still later date the downpour of not rain must have been very great indeed. This state of things must have continued for many thousands of year. I should like to hear what the learned men of America have to say on this subject. What was the maximum pressure and what was the maximum temperature during this boiling process? London, Righand.

#### The Evils of Price Cutting

The Evils of Price Cutting

To the Editor of the Scientific Ambarcan:
As we understand it, the object of the Sherman
Anti-trust Law is to prevent combinations in
restraint of trade. Strange to say, this law often
operates to secure directly opposite results. As
manufactures of proprietary remedies and as
wholesale druggists, we labored for years to perfect
and put into execution plans that would secure,
for the manufacturer of proprietary remedies, the
price at which we desired such remedies to be
sold and incidentally thus secure a profit to the
retailer and to the jobber. To accomplish these
unds, it is necessary that the three classes should
work together, that is, the proprietor, the jobber
and the retailer. This was accomplished and astifactory results were secured. The Sherman law
was then invoked and the work that had been

factory results were secured. The Sherman law was then invoked and the work that had been accomplished was decisared to be illegal, and since the issuance of what is called the Indianapolis Decree, each member of each of these classes follows his own particular course of merchandising. The object of the pyricisors, in endeavoring to maintain fixed prices for the jobber and for the retaller, was to secure a profit for these two classes, in order that they would, in the first place, stock his goods, and in the next place, have an interest in increasing their sales. The object of the jobber in assisting this plan was to secure a discount sufficiently large to pay the expenses of handling the goods and getting a small net profit. The sufficiently large to pay the expenses of handling the goods and getting a small net profit. The discounts ranged from 10 and 3 per cent to somewhat more. As the expense of doing business is about 11 per cent, it will be seen that the discount to the Jobber was not excessive. The retailer desired this protection-spo as to enable him to make a sufficient profit on the sales, of proprietary remedies to enable him to easiry time in stock. Another object to be socomplished by the proprietar was that, if a reasonable profit was secured to the retailer, he would not be lumpted to substitute. retailer, he would not be tempted to substitute. The successful enforcement of such protection would result in largely increased sales for projections and reasonable profits for retail distributors. The outcome of the Indianapolis Descene is that the outcers in the largest either have been enabled, because of their largest command of copied, to purchase goods at lowest prices then assignmented druggists and outsidered them. At the present moment, the business of a scale foreign to possibly one of the notice, prospecture of authorized them. As the present moment, the business of a scale foreign to possibly one of the notice, prospecture of the confidence of the confidenc

the sale of proprietary articles, the number of merchants dealing in those articles, in proportion to the population, is decreasing, the business is more and more being concentrated in the hands of large outers in large distributing centers, and the habit of substitution or of selling something "just as good" is necessarily increasing. The operation of the law the law has been, so far as concerns the

of the law has been, so far as concerns the sale of proprietary remedies, to defeat its own ends. In conclusion, it should be borne in mind that he retail price of proprietary medicines is stated on the label, and at no time has any attempt been made to charge the consumers more than the retail price as fixed by proprietors on their own

#### Fireproof Stairways and Elevators

To the Editor of the Scientific American: The Binghamion factory holocaust is only the logical sequence of a condition for which laws and ordinances

will always be inadequate.

win aways be inadequate.

To eliminate all danger of fire, churches, theaters and
workshops should preferably be one-storied, but never
more than two-storied, and provided, of course, with

the necessary means of egress.

Stair-wells and elevators will always act as funnels and propagate the fire and the smoke, even in the best nd propagate use are and an emotion, which is in the init freproof buildings. I would have, as shown in the secompanying sketch of a floor of a factory workshop,

Firepreof stairways, open to street.

all the halls, the stairs and the elevators entirely out on

The stairs would then be efficient fire-escapes, and the elevator, open on the hall only, with no direct opening whatever on any floor, could be operated and save lives during the fire. This arranger

ent does not take much more room than the present dangerous one, and procludes the necessity E BECKER.

Washington, D. C.

#### Suggestions on Utilizing the Power of the Missouri

To the Editor of the SCIENTIFIC AMERICAN

I notice in the recent issues of your paper that you are discussing the question of more efficiently handling the waters of the Mississippi and Missouri rivers in times of od. Of course, there will be various suggestions as to the best method of performing this class of public work I will suggest to you that I have been doing considerable was suggest to you that I have been doing considerable work on the subject of water-power and conservation of these natural resources. In a recent issue of your paper you make the statement that there are times when the Missour River washes much more sediment into the of the Mississippi River in a single year than the excavations amount to in the Panama Canal. If you were to examine the farms in this western country which surround a part of the Missouri River, you might easily surround a part of the anisoner rever, you make the com-see how a large part of this sediment is washed into the Missouri River. I have lived in a country close to the Missouri River for many years, and have noticed the serosion caused by flood waters, where guilholes and can-yous were washed out desper, and this wash that was your were washed out desper, and this wash that was taken out must have been in part delivered to she Missouri Rivor. I have seen small narrow canyons which were amouth in the bottoms and covered with grass, begin to wash right at the place where they would enter the oresit. This wash would cause a small waterfall, probably hos more than size eight indees in depth, but the continuous wear under heavy rainfall would gradually work hash toward the head of the capture. work back toward the head of the casyon. These guidnes would keep beaking down, and in a few root this wate-full grobably would become sight and ten feet in height. This has been the separiment of the farmers in the Mis-cagait River counter; said sill of this soil which is broken down in this way fland is in why fine the Miscouri and Mis-planding stores. This probably one of the courses, and the greatest course, of selfment washed family into the

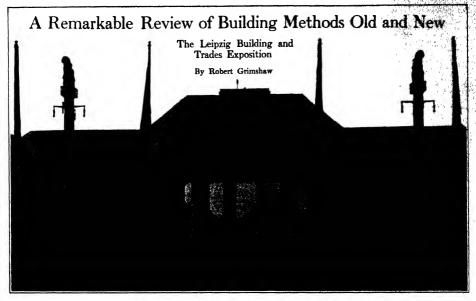

Mississippi River. There is still another source of sediment coming from the Missouri River. This great river ment coming from the Missouri River. This great river in times of flood will break through new banks, and in breaking through wash down a large amount of sediment and replace it upon the opposite bank or wash part of it on down the channel, but this source of washed sediment is not as great as the sediment which originally comes from the farms

Now the question arises as to how best to handle the waters of these great rivers so that the public works will be the least expensive and permanent in their construction. Reading over the comments from various source tion. Reading over the comments from various sources which have been printed in your paper. I have not hith-erto noticed any comments relating to the question or subject of water-power. Permit me to suggest that in improving these rivers for the purpose of carrying away the water in flood times, the question of water-power should not be overlooked. I am informed that the Missouri River is underlain with solid rock This rock is covered with a layer of quicksand and mud If any person cares to study into this subject of water-power, they may soon find that the Missouri River is a much better foundation upon which to build improvements for this class of work. There are reasons for this. First, the banks of the Missouri River are more narrow and higher than the banks of the Misslaslepi. If this question could sussed and the proper investigation be properly discussed and the proper investigations made, I believe that the conclusion would be reached that the proper method of handling these rivers is in connection with the subject of water-power. Dams might be placed across the Missouri River holding the water up from across the same remained water nothing and this would hold back the mad rush of waters at flood periods, and in addi-tion to that, every fall of water that might be obtained would be a source of water-power, and in addition to this water-power these dams might be so constructed that the Missouri River could be made navigable from the mouth of the river as far back as South Dakota. This would give opportunity for the shipment of millions of tons of give opportunity for the shipment of millions of tons of freight from the ocean to the inland states. In addition to those works, these little streams and creeks, which wash out the farmer's fields and carry them down into the rivers, might be stopped by the piscing of small dams where these breaks are found, and thereby prevent this large amount of sediment washing into the Missouri River, If you will take the time to look over that question, you will find that it is not so expensive to handle these rivers in this way as it would be to make great dikes and levees on the Mississippi River by which to carry away the flood waters. Now, in connection with this, I will suggest further to you the National Conservation Conference, which was held four years ago, and which made a report in three volumes, and the same was printed by the order of the United States Senate, showing that the available water-power in the United States amounts to about 230,000,000 water horse-power. If you will consult the United States census reports, you will find that the total amount of horse-power used in our industries throughout the United States amounts to about 18,000,000. now using in the United States in the several industries about one thirteenth of the available water horse-power which we now have and which might be utilized for future generations, if these rivers could be handled in the way that I am now suggesting, and the electric energy deliv-ered and sold to the people of the country at \$20 or \$25 per horse-power per annum. The revenue derived from this source of income would be sufficient to pay all of the taxes of the general Government and of the states and the counties and the schools and all municipalities, and it would be a paying proposition to the Government from the day in which the first water-power could be placed in operation by the methods which I have suggested Other ers do not suggest the utilization of these waters in such a way that they may be a source of profit to the country rather than a source of expense. We are ap-proaching the time in this nation when the question of coal and oil is going to be a serious matter, and these water-powers should be utilized, and an investigation upon this question should be undertaken at an early date for the purpose of finding the real facts as they exist. I wish that you might go over this question, as I have sug-gested these matters to you, and I believe that if this question were placed before Congress in a proper way. appoint a competent commission to give this matter a ost thorough consideration and find the best methods e we spend any money on actual construction.

I believe that the greatest imperfection of the American people lies in the fact that they never apprehend a necessity until they are actually in need. That is our necessity until they are actually in need. That is our condition just at this time in respect to the conservation of our oil fields and the coal fields and these natural resources of water-power. I was before the Legislature this winter in the State of Nobrasks, and undertook to impress that body with the importance of the question of water-power in this State. The question is new and has not been widely discussed, but we must meet the situation in the near future and take this subpact on for has not been widely discussed, but we must meet the situation in the near future and take this subject up for discussion and utilize these water-powers for the conser-vation of our oil and coal.

Walter Joenson. vation of our oil and coal.

University Place, Neb.

Entrance from the Reitzenhainerstrasse through the column portal of the Administration Building.

DEMONSTRATING the intimate relation between science and indus-tity, a characteristic of modern national or international exhibits, the Leipzig Building and Trades Exposition, which opened the inddle of May, to continue until the end of October of this your, is by far the most important attraction of the year in continental Europe, although it is also of world-wide interest. This exhibition follows ideal rather than industrial lines, its

object being to distribute new thoughts, som in 1900 the number of buildings in reinforced concrete showed the progress of French engineers in this line.

The grounds lie southeast of the city proper, and permit ratiway connection for the exhibits right up to the buildings. The greatest width of the exhibition grounds, that from one corner of the amusement part to the main entrance, is 2,624 feet.

Classes of Exhibits.
In the exposition there are eight main classes of exhibits, as follows:

I. The constructive arts: 8 groups, divided into

33 sub-groups. II. Building literature, building-trade

school, office furniture, 3 groups.

III. Building materials, their manufac ture and use; 20 groups, 24 sub-groups.

IV. Machine tools and appliances the building industries: 5 groups, 2 sub-

V. Real estate and transactions in con nection therewith; information and insurance; 5 groups.

VI. Building hygiene for dwellings, factories and streets; protection and welfare of work-people; fire-protection; 6

groups
VII. Gymnastics, games and sports.
VIII. Tests of building materials; expert demonstrations.

The Scientific Department, to which over 50,000 square feet of surface is de-voted, covers four departments as follows: I. Scientific carrying out of construc-

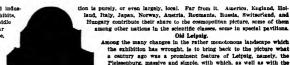

Artistic execution of above-ground constructions and their surroundings.

III. Scientific and artistic execution collective building projects (city building, settlements, colouization).

IV. Hygienical and sociological precau tious in the building trades, etc. (Protection of workmen.)

Many Countries Represented.

It must not be imagined for a moment that although Leipzig is no metropolis of trade or center of diplomacy, the exhibi-

old Rathbaus (City Hall) the history of Leipzig is interwoven.

In his design Drechsler shows not only this old citadel with
its immediate surroundings and the Peter's Gate, but the Grimma Gate and the adjoining University Church and Dominican cloister.

The Machinery Hall.

The Machinery Hall has an area of 55,500 square feet and contains all kinds of machines for making and working building materials; also overhead cranes and other transportation devices. The central light and power station, supplying the entire exhibition grounds with current, is located here; there are two

Diesel motors of 1.120 horse-nower es direct coupled with two dynamos of 750

Statistics in Building Operations.
In order to show the importance of collecting statistics of building operations, there is a special exhibition in this line, there is a special exhibition in him, may, particularly as regards engineering work and political economy. Engineering statistics, especially concerning foundation and overhead building, are well repreand overhead building, are wen repre-sented. Statistics concerning political economy are in charge of specialists. The engineer's hare in the general work of civilisation also comes in for representa-

The City of Leipzig Exhibit.

The city of Leipzig is taking a very active part as exhibitor in the exposition.

There is shown by the municipality a project for the regulation of high water in the western portion of the city; the municipal systems of sewers, gas and water pipes and underground cables; graphical representations of the method graphical representations or the methods of laying out, paving, maintaining and cleaning the streets; the standard systems of design and construction of buildings; and very full graphical representations of the statistical, sanitary and other dements of the municipal government.

THE PROPERTY OF THE PARTY OF TH

Terrace in front of the bridge over October 18th Street. Monument of the "Battle of the Nations" in the background.

collection of models and drawings of engine consection or motess and drawings or engineering con-struction—much more couplete than at previous exhi-bitions. The Saxon State has its own pavilion, and besides this, an installation of safety appliances for railway purposes. Then the governments of Bavaria, Wirttemberg, Hessen and Elsass-Lothringen (Alasca-Lorraine) have special groups. Roumania has its own building.

The Saxon government building fronting on Linden Avenue covers about 10,000 square feet. In this building the state railways and the electric railway com-mission show a full and varied collection of material in their respective lines. Among other exhibits are models, drawings and photographs of new and old bridge constructions, the oldest tunnel in

Germany (at Oberau), many rafiway sta-tions and many noveities in signaling

American Exhibits.

The city of New York is exhibiting models of the East River bridges, and of skyscrapers, models of dwellings of the rich, middle and poorer classes. There is a plan showing the building operations and a large photograph of the city as a and a large photograph of the city as seen from the harbor. A further exhibit is the water supply and the public baths. Mr. Cass Gilbert, the architect, is displaying a model of his 63-story Woolworth build-ing, the model friedf being "Made in Ge-many." Mr. Hornbostel, one of the Carnegle engineers, has also sent a number of interesting models of buildings de-signed by him and erected in New York

Other American municipal exhibits are those of San Francisco, Chicago, Phila-delphia and Washington. The American Bridge Company and the Canadian Rail-way Company also have exhibits.

Art in the Leipzig Exhibition.

The exhibition would be incomplete without a department for pictorial and plastic art; and in order that this may be both full, yet select and representative and worthy, the association of Leipsig artists has a display in two special rooms They exhibit a selection of the pictorial and plastic art of the last thirty years. The importance and character of the ar-hibition may be judged from the mames of some of those whose works are shown: Femerhads, Böcktin, Mennel, Hedler, Leibl, Stuck, Liebermann and Klinger.

It is not to be expected that the head and ounter of the publishing and book-sal-ing interior of Germany, if not of conrmany, if not of con-original interest in this. The technical litera-

nected therewith is strongly represented, but in an en-tirely different and more extended manner from that adopted at previous international and local exhibitions.

adopted at previous international and local exhibitions.

Suscial Agricultural Exhibition.

Eastward from the amusement park comes the special agricultural exhibition, which is of great industrial interest and importance, especially as it shows the various types of structures used for all sorts of agricultural purposes in various countries and districts. In our particular, especially, is it worthy of notice—that of stables; for it has been proved that stable architecture and construction have great influence on the soneral health of the animals, and expecially the general health of the animals, and especially on their powers of resistance to infectious diseases.

View of the Grintma Gate and old La

The Garden City or Garden Suburb "Marienbrunn."
One special feature of the Leipzig exhibition is the farden City or Garden Suburb, the development of which idea is taking place with more or less satisfaction and financial success in various countries and districts.

The present subject is a new and made-to-order "citylet" about a quarter of a mile from the main building of the exposition. It is designed and bullt according to proper sanitary, social, economical, technical and exthe-tic principles. There are seventy-two houses, some for one family, some for more than one, renting for from M. 250 to M. 1,250 (\$59.50 to \$207.50) per year.
The present exposition at Leipzig may be considered

in the light of a response to some of the suggestions brought out at the Dresden Hyglene Exhibition of 1911. Then it was shown how the inhabitants of a town or city are interdependent, while the present exhibit points out how the greatest good to the greatest number may be attained by organized endeavor through municipal and state institutions. A more extended article on the exposition appears in the current issue of the Scientific American

#### Effect of Radium on Plants

Hill seleutist H. Molisch finds that radiam rats have the effect of interrupting the repose of winter buds of different woody plants and thus give rise to a preocious budding. Thus the terminal bu of the Syringa rulgaris when exposed to the effect of strong radium saits are found to develop soon after, and this even during the month of December, when the plant is cultivated in a hot-house. Untreated buds do not unfold, or at most this occurs much later. It is required to determine the time of exposure to the radium very exactly, and should this he too short there is no action produced, while a long exposure is injurious and even mortal. Radium effects are not felt either at the beginning or the end of the repose period. The emanation from radium is also used, and it acts even better than the rays from radium saits, as the effect is more diffused and uniform. When used at the end of November or early in December it will start the buds of Aesculus hippocastanum, Staphila pin-nata and several other plants which were tried. Others like Platanus orientalis, however, give no results. Although the radium salts are too expensive to be used ctice for this purpose, the results are of interest, especially as strong rays from radium do not appear to have the same action upon plants in full growth as they have during the repose period.

Mixing the Danyss virus with grain. Fatal only to rodents.

### The War Against Field Mice in France

By Jacques Boyer

Aremic, barium carbonate, and bisulphile of our bon have been used with more or less success in destroping field mice and sinklar pests. The method now most favored consists in infecting mice with a contagious disease. In the following article the Danyez virus discovered at the Pasteur Institute of Paris and applied for this purpose is described.—Eutron.

Pineing virus-infected grain at the mouths of the

A T the present time France is overrun by field mice and their congeners to such an extrordinary extent that it has heen found necessary to organize an official war of extermination against them. According to information collected by the Ministry of Agriculture the voracious and destructive rodonts have invaded fourteen departments of France (Ain, Alsse, Ardeniues, Aube. Belfort, Cole d'Or. Doubs, Haute-Marne, Jura, Muerthe-et-Mossele, Menus, Suvole, Haute Savole, Vosges). They attack all crops, devouring clover, uncerea and sandrion as well as pring grain, bests and Jerusalem artichokes, and do not expare even the bude of isolated vineards and support for the rest.

The most destructive of the rodenis are the field rut (Arteloia gorestic) and the field must (Arteloia gorestic) and the field must (Arteloia gorestic) and the field must (Mus spitesticus) At irregular intervals, as in the pre-sent year, these peets appear suddenly in immones numbers, in midsummer, and vanish as mysteriously, but not with out leaving insurantial transmission of titler vialt. These formidable little animals have cost French farmers autoid millium Since

formidable little animals have cost French farmers mitted milliams Since the commencement of the nineteenth contury they have made at least a dozen serious incurdons, the most disastrous of which extended from the summer of 1801 through the autumn of 1802. In three departments the crops were annihilated and the meadows completely rulned.

A commission appointed by the Academied eas Neiences to dethis means of combating the securge outlinated the loss smentured by the single department of La Vendée at more than half a million dol lars. In 1822 the rodents increased predictionally in Alsace and more than two millions of them were killed in two weeks of the vigorous warfare waged against them. Many similar examples might be cited. The average annual loss caused by those field peats in France is estimated at forty million dollars.

In order to discover rational methods of combating these destructive sulmals it is necessary to uscertain the causes that give rise, intermittently, to their immen and often widely disseminated hord Formerly it was believed that the rodents were migratory, for in many instances few of them are seen in the year preceding a great invasion, and still fewer the year after the invasion. But the obervations of Crampe, Ritzoma Bos, and J. Danysz have made it certain that the members of even the densest swarm begin life very near the scene of their depredations. They may invade adjoining fields when they have exhausted the resources of their hirthpines, but they never emi-grate in great numbers. The intensity and suddenness of their visitations must be attributed to the extraordinary fecundity of these animals, which is increased by the numerical preponderance of females. Danysz has calculated that one pair of adults may produce, between February and the end of autumn, a progeny of 200 females and 100 males. Hence n rodent population of 150 (an almost inappreciable number) existing in a hectare of land (about 2½ acres) in February, may increase to 10,000 in July and to 20,000 in September by their normal multiplication

Portunately, the animals born in late summer and autumn do not attain their full development until winter, and most of them prelish in the first severely cold weather. On the other hand, young litters and prejmant females are killed by late spring frosts, following several days of mild dry weather. The rodests are not continually hunted and destroyed by Dirds of prey and by moles, shrew-moles, hedgehogs and other antimals

Finally, when these various destructive agencies fail, the rodents perish in consequence of their own enormus increase. If they are too numerous in any place, they become weakened by lack of food and fall an easy prey to feas, ticks and fungus parsaits, which produce fatal epidemics in the active and voraclous best.

These assertions are corroborated and a new light

Field-monee (Mus sylvatious).

Field-rat (Arvicele agreetie).

Georrapain, and Demoion, of their size in the control of the thickness of the control of the control of the thickness of the control of the control of the thickness of the control of the the destruction of every focus of invasion, as soon as it is discovered.

Effective methods of destroying the formidable rodents have long been sought. At first, poisoning with arsenic was recommended. A mixture of areatic and four is stirred into a quantity of wheat moistened with molasses, and the poisoned grain is placed in drain tilles of small caliber which are distributed through the lifested fields. Some writers advise placing the poisoned grain in the rodents burrows

poisoned grain in the rodenta' burrows and stopping the outrances with earth. This method yields imperfect and uncertain results, for the rodents often refue to eat the poisoned grain, which they scatter around their holes, where it may be eaten by ponitry and game birds. Arsenic, moreover, is intensely poisonous to all animals and to human beings.

It is better, therefore, to use the barium carbonate bread invested by Dr. Hitner of Munich. Four parts of chesp flour and one part of barium carbonate are mixed with water and yeast. The dought is allowed to rise and is based in compact hard loaves about 1½ inches thick. The bread is soaked in satismed milk or spitchied with essence of sinseed and is broken into pieces as big as a heasing, one or two of which are put into each burrow. It is asserted that little more than one pound of bread to the arre in required to rid a field of rodent pests, so that this method is both cheep and

In Denmark, in 1910, a method of destroying field mice with biardphide of carbon was introduced by E. de Kruyff. All orifices of the Burrows are stepped at might, and on the following night one or two cubig continuences: (thimbierhie) of bianishible, of chrobn are poured into each new opening that the mine have made. After waiting a few seconds to allow the liquid to evaporate a lighted tooch is applied to the hole. The beautiphide experiments and explodes, filling the burrow with polasmost gases, which instantly, this its demiseas. One pound of biantphide is carbon is enough for more than 900 herrows. Although this method is viery effective it is also output for more than 900 herrows. Although this method is viery effective it is also never of electric said dangeous when applied by carpless or inseparelected persons, because of this gapit inflatmantability of the bisusphide representation of the control of

and the state of the

The heat was so intense, it was necessary to open the dears with large iron rods.

### Fire, Load and Water Test of Floor Arches

An Interesting Test in Which the Qualities of Gypsum, Terra Cotta Tile, and Reinforced Concrete Were Tested for Several Hours in Fierce Heat

Huge concrete firebox in which heat was kept at 1,700 deg. Fahr, for four hours.

A N interesting and conclusive demonstration of the A fire resisting qualities of various building materials used in Store crebs, was made on Wednesday of last week by Mr. Harold Perzine of Columbia University, at his testing station in Greenjouta, Long laisald. There were three arches built especially for this test. One of these was built up of 4 these of reinforced gypsum and sharings with a 2-inch cinder fill, another consisted of 50-inch holious term count tile with a 4-inch cinder fill, while the third arch was a 4-inch reinforced cinder concerte also with a 2-inch cinder fill. In each case the cinder fill consisted of one part cement and na parts cinders, while he concerts was composed of one part cement, two parts and and five parts cinders. The reinforcing material in the grpeum and converted material in the grpeum and converted materials in the grapeum and converted with a 4 to the first converted was contracted with a 4 to the first converted was converted to the grapeum and converted the grapeum and g

The arches were each 5 feet 3 inches wide between the center lines of the beams, and 14 feet long, consitueted over a 14 by 20-foot concrete drabox in such a manner that the under sides of the arches were directly exposed to the fames. In the walls of the firebox were six flues, three ou each side, in order to provide a proper draft.

At 11 A. M. a hot fire was built on the grate and

At 11 A. M. a bot free was built on the grate and neveral workness were kept buy piling in cord wood to keep the temperature up to 1,700 deg. Fahr. This temperature was recorded and maintained by the use of electric pyrometers, fron tubes being placed at various points in the roof or arches for this purpose. This was continued for four hours, readings being taken frequently by means of a surveyor's level, located on a nearby roof, for the purpose of assortaining the deficetion in the arches due to the intense heat.

It should be added that the arches were constructed in strict accordance with the requirements of the building department of New York city, and even the allowable load, to which stoors are restricted, was added. This was done by pilling rist from on top of the arches, as is clearly shown in the illustrations, until the load reached 150 bounds per square foot. There were no partitions inside the firebox and each arch was subjected to the same amount of beat during the entire four hours of the test.

At the end of the four hours a division of the city

At the end of the four hours a division of the city for department was on hand to extinguish the fire and cool the walls and arches. The firement turned a stream of tremendous force against the hot firebox and finor arches and made short work of the fire. There was a water pressure of 60 pounds per square inch from a Uki-the hours!

It was a surprise to many who witnessed the performance that the arches stood up as well as they did, considering the high temperatures and very sudden confidering the high temperatures and very sudden collag to which they had been subjected. The term stood the collection of the collection of the collection to the collection of the but the arch did not give vary, as was predicted by servval of the witnesses after the test had been running two hours. It was also noted that this arch had defacted one inch from the level, while the others were undisturbed.

The gypsum arch was intest above the reinforcing stool, although it had crumbind away below this. Considering the nature of this material, and also that it was mixed with wood shavings, it stood up remarkably well, even with the 150 pounds per square foot of lead. As was expected, the concrete arch showed no great effect from the ordeal to which it had been subjected. It had not even crumbied away from the reinforcing steel, and had showed no appreciable defection.

by the fact that it was attended by more than a hun-

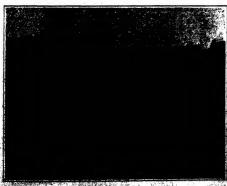

dred men, including engineers, architects, contractors, and dealers in fire-proofing and reinforcing materials, as well as several representatives of engineering and scientific publications.

#### Gasoline Substitutes

LEWEN in the Chemical World, 2,113, predicts that the waning supply of gasoline will very soon force the use of alcohol densurated with ten per cear of benzol. This will be safer, more pleasant to use and sweeter in exhaust than the gasoline of to-day. Though the caloride value of this mixture is only six touths that of 'perrol' or gasoline, the higher compression possible and increased explosive range will make it the ideal motor spirit. Benzol itself is being seriously considered as a substitute. It is twolve per cent more powerful in running than passoline and Binglish coke over plants yield 8,000,000 gallone as a by-product. The cummer-call product contribing, as it does, 150 grains of sulphur per gallon needs cureful purification for motor use.

#### Sugar as a Surgical Antiseptic

IT has long been known that sugar was a disinfecting and preservative spent. The fact is even said to have been mentioned by Galen. But it is rather novel to learn from Lo Revue that an eminent German surgeon, Dr. Georg Magnus of Munch, who is famous as a traumatologist, recommends it strongly as a dressing for wounds. All saccharine substances are good, but pure cane sugar or heel sugar is best. Its disinfecting and sterilising qualities are excellent. It is not injurious to the blood, as has been wrongly believed, and is a better preventive of putrefaction and contamination by microbes than ordinary modical antiserdies.

A weight of 194 persons per equals

After the four-hour test fremen were called to extinguish the flames and to

#### The Industrial Need of Technically Trained Men-VI A Study of Incomes of Technically Trained Mon

By David Edgar Rice, Ph.D., Secretary School of Science and Techn Pratt Institute

ie income is naturally a factor of considerable importance. This factor is very often veiled under the more general term "opportunity," but opportunity means simply the active demand for the service offered, and where labor is concerned, this

the wage. Educational institutions that offer a variety of courses of training are frequently called upon by prospective students to give some statement as to the ing? Is the mining engineer more likely to secure profitable employment than the

se and similar questions may be co sidered from a theoretical point of view. but as the proof of the pudding is in the eating, so the most direct and convincing answer to such questions is to be derived from a study of relative incomes, where curate information is available.

The School of Science and Tech of Pratt Institute, Brooklyn, N Y., has ently completed an investigation of this character. The data have been gathered from more than one thousand men who, within the past nineteen years, have comcourses are two years in length and cover the fields of mechanics, electricity and chemistry. They do not profess to be engineering courses, but are rather of the so-called "industrial" type, offering technical and practical training intended to prepare young men for positions of re-sponsibility above the grade of skilled mechanic in mechanical, electrical and chemical manufacturing and industrial

The men enter these courses at an average age of from eighteen to nineteen years. Some of them have had three or four years of a high school course, but little or no practical experience. Many of them, on the other hand, have had a considerable amount of practical experience, but are without the preparation af-forded by a secondary course of study. The data here presented, therefore, in-

dicate the earning power, which may, on the average, reasonably he expected by intelligent, capable young men in these in-dustries who have taken two years to train themselves technically for the positions of more importance and responsibility than those of skilled mechanics.

The information was collected directly

from the graduates themselves. Each graduate was asked to state his innot in exact figures, but by means of code letters covering a fixed salary range. Be-low \$1,500 each salary group had a range of \$250. Above \$1,500 the range was \$500. edian of the range of each group was taken as the actual figure in making up the average. To this extent the figures here given lack absolute accuracy. The error possibly resulting from this cause was to some extent offset by plotting the average incomes of the different classes in graphic form, drawing a smooth curve gh the several points, and taking off the averages from these curves.

The tables herewith given show the average incomes of the graduates of the several courses for each year after graduation, the average incomes of the 20 per cent of each class having the highest incomes, and the average of the 20 per cent having the lowest incomes. For the mehaving the lowest incomes. For the me-chanical course, the so-called course in steam and machine design, the period since graduation ranges from half a year to eighteen and a half years. For the course in applied electricity the maxi-mum period since graduation is fourteen

N the choice of a vocation, the prob- are comparatively small in number, and that the returns from these classes also are less complete. The data for these classes are therefore somewhat less re liable, representing averages made up from the experiences of comparatively few individuals. For classes that have been out more than ten years, the number of men represented is less than twenty

For classes out less than ten years the er ranges from twenty to forty-five. Table I gives the facts for the grad quentry caused upon by prospective sub-dents to give some statement as to the relative opportunities in different lines of design, the oldest course in steam and machine work. Loss electrical engineering offer a broader field than mechanical engineer class. It shows that at six months after class. If shows that at the labels and graduation, when practically all members of the class may be presumed to be fairly well settled in their positions, the average ne is approximately \$875. For period of about ten years after graduation the annual rate of increase is practically uniform, and is, on the average, abou \$140. At this point it becomes noticeably less, being reduced to an average of ap proximately \$100. It is, however, interes ing to note that even to the last there i a constant increase in the annual income indicating that the men who have been out in practical work for more than eighteen years since their graduation have not yet begun to reach a limit to their earning capacity—a very strong argument in support of the advantages of tech

> The second and third columns give the average incomes, respectively, of the higher fifth and lower fifth of the severa classes. They serve merely to show the salary range and call for no special com-

nical training.

for graduates of the course in applied electricity. The average income for the entire class is practically the same as fo the graduates of the mechanical course except that the initial income is slightly This difference, however, disappear

within the first two years.

A comparison of the figures for the upnd lower fifths of the clas that the range for the electrical course is siderably less than for the mechanical While the incomes of the more successfu electrical men do not run so high as thos of the more successful mechanical men, the averages for the less successful, on the other hand, do not reach so low a

A comparison of the average inc for these two courses is interesting in connection with the question as to which field the mechanical or the electrical, offers the better opportunities for advance The prevailing impression, at least am young men who find it necessary to make a choice, seems to be in favor of the elec-trical field, but the facts here presented

do not support this view.

Table III summarizes the facts for the course in applied chemistry. This is the most recently established course in the school, and had only six classes of gradnates at the time this information was gathered. The striking fact in connection with this table is the rapid rise of the average salary in comparison with that of the other two courses. Although the initial income is practically the same for all three courses, the chemistry graduates reach the \$1,500 point almost two years earlier than do the graduates of the other courses, and they reach the \$1,900 mans nimost three years earlier. In explanation of the better showing

made by the chemistry graduates, several factors are to be considered. In the first place it seems to be the fact that the training in industrial chemistry can be to eighteen and a haif years. For the results of the state of the stat

sort of preliminary apprenticeship is necessary before they can develop a high degree of efficiency

In the next place it is undoubtedly true In the next place it is undoubtedly true that the supply of men trained for work in industrial chemistry is considerably less than in the mechanical and electrical fields. It is only recently that the possi-bilities of the industrial chemistry field have begun to be resilized Comparatively few institutions offer courses in chemical engineering and comparatively few men graduate from these courses

Another factor to be considered is that

in the chemical fields the transition from the status of employee to that of em ployer or proprietor is probably easier The business of manufacturing chemiss on a small scale may be established with much less capital than is usually required for enterprises of similar character in me

In comparing the facts given in these tables with corresponding data from other institutions, it should be borne in mind as has already been pointed out the these are not engineering courses but two year courses of practical character intend ed to give the essentials of a tecl education to men who have had but little are compelled by circumstances to work their way upward from the ranks

#### Neglected Subjects in Medicine

A NYONE who turns the pages of the huge Index Catalogue of the Library of the Surgeon General's Office United States Army, of which 23 volumes have been published up to date and which is seen paintains up to date and when as a practically exhaustive catalogue not only of medical books, but of articles in the medical journals of all countries, might gather the impression that greey medical topic of the alightest importance

madical topic of the slightest importance had been fully investigated and writton up. This is, however by no means the case, for many such topics of very con-address to the considerable importance have been almost completely neglected. We recently called attention in these columns to the fact that hardly anything is known about the six ture and causes of "astraphobia," i. a., the pathological effects experiessed by many persons before and during thunder-sions. An analogous cans be that of "assisrophobia," or mortisi antipathy to

# The Ten Greatest **Inventions of Our Time**

We hear much of the great inventions of the pastthe telegraph, the sewing machine, the telephone, the reaping machine, photography, Bessemer and open hearth steel, the steam engine and the phonograph. Yet the inventions of our own time are as epoch-making and as dramatic as these.

Perhaps because we have become accustomed to the use of the old machines and discoveries, perhaps because the achievements of latter-day inventors succeed one another so rapidly that we are not given much time to marvel at any one of them, we have not fully realized how stirring and wonderful are the products of modern ingenuity.

Only five years ago the man-carrying aeroplane made its first public flights; only the other day hundreds of passengers on a sinking ship were saved with the aid of wireless telegraphy. At least a dozen inventions as great have been perfected in our own time, and all of them have made a man's work count for more than it ever did before, and have made the world more livable than it ever was.

Why should we not tell the story of our own deeds? Why should we not review the industries created by men who are still living, men whose names will go down into history with those of Watt, Morse, McCormick and Howe?

That was the underlying idea of the November Magazine Number of the Scientific American. We knew that the "ten greatest inventions of our time" was a big subject when first we planned the number, but how big it was we never realized until we surveyed the field of modern invention.

Then we saw how astonishing was the progress made in our own day, how much mankind had benefited by the inventions of great modern intellects. We began to appraise inventions, to weigh one against the other, and to determine in our own minds which ten had contributed most to human progress and happiness, which were really great pioneer inventions, and which merely remarkable and valuable improvements on successful past conceptions. There were so many achievements to consider that it was hard to arrive at a definite conclusion.

The upshot of our own thinking has been to leave to our readers the decision

### What Are the Ten Greatest Inventions of Our Time. and Why?

For the Three best articles on the subject, the Scientific American offers in the order of merit, three cash prizes:

First Prize: \$150.00 for the best article Second Prize: \$100.00 for the second best article Third Prize: \$50.00 for the third best article

See page 86—last week's issue—for conditions of the Contest.

ests. What little is knows, scie on this subject is almost entirely due to Dr. Weir Mitchell, and his rather fragcomparatively recent; whereas the ci tion in question, like that connected was thunderstorms, is neither novel nor un familiar in its non-eclentific aspects; profamiliar in its non-scientific aspects; prop-ubly there are few readers of this journal who do not number several "seture phobes" among their acquaintances. How does it happen that there is not an exten other subject that has been greatly ne glected is dermatitis venenata, especially in connection with plants. Dr. 3. O. White's book on this subject, published is 1887 and now out of print, is the unique ographic treatment of the questi How many people, even in the medica profession, realize that upward of 60 com on species of plants growing in the United States are more or less poisonou to the touch? The attention of the publi in this connection, has been strangel opolised by poison ivy and its ec

#### Field Mice

(Concluded from page 114.) bisulphide vapor kills most of the mice and the destruction is completed by reand the destruction is completed by resulting the application, on the following night, to the few holes that are again found open. This process may require right or ulue pounds of bisulphide per acre. The suffocation of the rodents by sg their burrows with sulphurous acid and other gases requires the use of cum

The method of destroying rodent field ests which is now most favored consists infection with a contact of in infection with a contagious dis In Germany the Loeffler virus is used. In France, the Danysz virus has been adopt ed after many experiments. The Danyss virus, which is nearly related to Lossi is prepared at the Pasteur Institute an siso by departmental veterinaries. Its Typhimurium), which Danyss found in the bodies of field-rats, in 1893.

Experiments continued through several years have led Danysz to recommend the following method of employing it: The virus, diluted with sait solution with rolled oats or crushed wheat or barley and allowed to ferment for three or four hours. A small quantity of the mix the burrows The virus is supplied in litthe bottles, each of which, with 22 pounds of grain, ½ ounce of sait and 7 pints of water, suffices for the treatment of one of water, sunness for the treatment of one hectare (2½ acres). The period of incubation of the disease is ten days, and the mortality is 85 to 95 per cent if fresh virus has been used. Virus more than four days old, on the contrary, n fails to kill the rodents, but it "fattens" them, as the farmers say. Denon has proposed to assist the action of the virus by adding barlum carbonate to the i ed grain, but this proceeding has not bee of the Danyez virus alone has received both popular and official sanction in France, and also in Tunis, Hamburg,

Copenhagen, and elsewhere.

The virus can be obtained with culty from the Pasteur Institute, wh special laboratory, which can furnish ch can furnish sev eral thousand bettles of virus per day, has been established. The French railway companies have agreed to forward the virus by fast trains at a very low tariff. The cost of treatment, therefore, does not rue cost of treatment her never does not exceed fifty cents per sere. This method, which is the only one recommended in the intest circular of the Ministry of Agriculincest circular of the animatry of Agricul-ture, possesses the great advantage over all others that the grain infacted with Danysz virus is harmless to domestic ani-mals, birds and the men who distribute it.

male, birds and the men who distribute it. If satisfactory results are not destanded in two weeks, however, Guerranain, and Demolou advise the employment of arsenic, and if this size falls, the use of blutphide of earton, two weeks laker, by treatment, by successive somes, including hodges, groves and coker further states.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

#### Sea-level Canal Fallacies

HE rupid increase which is taking place in th dimensions of the largest steamships built for the Atlantic trade—the fact that vessels exceeding 900 feet in length are now either actively engaged in service, or are approaching completion by the build-ers, has led to a revival in the public press of the arguers, ms ted to a revival in the pulsor press of the argu-ments which were used several years ago in favor of building a sea-level cauni at l'anama. Attention is drawn to the fact that since the "imperator" is 680 feet in length over all, and the "Vaterland," which will visit this port next spring, will be 940 feet in length, and a third vessel, now on the stocks, will be even longer, the time is approaching when the usuble length of 1,000 feet of the locks of Panama will be found i ficient to accommodate the largest ships of the mer-

Would it not have been wiser, say the critics, to inve built the Panama Canal at sea level and thus have pro-vided a channel, free from obstruction, through which the world's shipping could pass at any time without let

Now the pros and cons of this problem were very Now the prox and cons or this problem were very thoroughly entered into by the Isthmian Canul Com-mission when it was preparing data for the guidance of Congress in reaching a decision as to whether the canal should be built with locks or at sea level. So far as the professional mind is concerned, we doubt if any engineer could be found to-day who would advocate the construction of a sea-level canal at Panama; but since the question has been raised and agitated in the lay press, we will re-state, briefly, the conditions which render a canal at sea level both technically and commercially impossible.

In the first place, then, let it be clearly understood that any kind of a canal at Panama must perforce be provided with locks; and this for the reason that the great difference in level of the Atlantic and Pacific oceans renders at least one set of locks necessary. The extreme rise and fall of the tide at Colon on the Atlantic is about 2 feet; at Punnus on the Pacific it is about 22 feet. At mean tide the two oceans are at the some level, but at extreme high tide the water at the Pacific end is 10 feet higher than that at the Atlantic end, and at extreme low tide, it is 10 feet lower. no regulating locks were established, let us say at the Pansama entrance, the difference in level at high tide would cause a heavy current to set up in the Causi from the Pacific to the Atlantic, and at low tide there would be a heavy current in the reverse direction would render navigation difficult. for should a shire sound remove management of macute, or should a single say 600 or 700 feet in length make a sindlen sworte for either bank when she was breasting this current, it would be difficult to prevent her taking the ground. A single flight of locks at the Pacific end would be an absolute necessity.

The Panuma Canal locks are 1,000 feet long and 110

feet broad, and the breest ship built to-day is 940 feet long and 100 feet broad. A ship of this size, then, could long and 100 feet broad iong and not rect broad. A sinji of this size, then, could use the Canal comfortably, since it would be taken through under the absolute control of four powerful, electric, towing locomotives. We think it is very doubtelectric, towing locomotives. We think it is very doubt-ful if these dimensions will be exceeded for many years to come; but even if they should be, and vessels of 1,000 feet length should be built, they would have no relation to the groblem under consideration; and this for the reason that ships of this size are built solely for the heavy damastizatic passenger trafts, and only in such service can they possibly be made remunerative. Not within the life-time of the youngest child that our

Not within the life-time of the youngest citied lane one, special out what is here being written, will there be in call for such ahipe on the various rentes which seek or will seek to pass through the Panama Cápāl.

Nature itself, however, has decreed that no sea-terel canni shall ever be constructed at this Jatimus; and in fast is to be read in those enormous masses of unstak!—material which, unsettled in their age-long equivalent to the property of the pro illurium by the digging and delving of man, are now moving slowly but with irreststible force into the cana moving slowly but with irrestatible force fint the canal priam. The problem of removing this material is very serious, it is true; but the skill and resources of the oughierer are equal to the task. The Canal will be opened ou time; an unobstructed channel for the pas-sage of skips will be maintained; and the work of transporting the débris will continue, until the last cubic yard has alipped into the channel and been removed. Then, when the angle of repose that has been ordained by nature has been reached, the Canal may

We are speaking, bowever, of a lock canal with its surface 85 feet above the surface of the adjacent oceans. If our engineers were now engaged in constructing a scu-level canal, the bottom of the excavation would have to be carried down 85 feet below its present level, and throughout the whole nine miles of the Culebra section an enormous additional slice of material would have to be taken off the slopes on either side of the canal prism. It does not take a professional mind to understand that sliding, which is so serious in a cut of the present depth, would become absolutely over-whelming were that cut carried 85 feet farther down, and the equilibrium of the mountain divide proportion ately disturbed. As matters now stand, sliding has been such that at one point, where the proposed slopes either side were three vertical to two horizontal, the flow of the treacherous material has been such that the present slope is one vertical to seven horizontal, and the whith of the cut at the natural surface of the ground has widened out from 670 feet, as planued, to a ent width of 1,800 feet.

present wath of 1,300 rose. In view of such conditions as now exist, it would not take a hold prophet to state that if the cannal were cut through the divide down to sea level, both the time and the cost of construction would be doubled.

#### Japan's Battle-cruiser Squadron

STUTENESS is a pronounced characteristic of the Japanese character, and nowhere is the sagac-ity of this people shown to such good effect as in the up-building of their navy—in which enterprise they have made few, if any, mistakes. Hence, we may rest assured that it was not without very good reason that the Japanese Government entered upon the construc-tion of the four powerful and very costly battle-crulsers, the first of which forms the subject of illustration and comment on another page of this issue. Our Navy Department, it is true, regards with disfavor my proposal to build high-speed battle-craisers for our service; holding that, in view of the limited appropriations which are available, it is best to put such moneys as are appropriated into battleships carrying the heaviest armor; since it is by such ships that the final decisive stroke of a naval conflict must be given

it may be that the Japanese strategists, having in view the conditions which would prevail in the event of hostilities with the United States, believe that they nid deal the most telling blows if a consider of the displacement of their new construction were embodied in a number of ships of great gun power of sufficient speed to elude our battleship fleet and acan engagement as the conditions see favorable or otherwise to their succe

No one who makes a study of the "Kongo" and her three sisters will deny that the quartette will add to the Japanese Navy four identical ships whose poten-tialities are very formidable indeed. A squadron whose thirms are very rormanous messed. A squarron wassess batteries agargeate 32 of the most powerful naval grass afoat, and whose speed is such that these batteries can be carried from point to point at 28 knots sustained see speed, and whose fuel supply of 5,000 tons of oak and oil will be sufficient, surely, to enable them to cross the Pacific and return without replenishment, forms a fighting unit which may well give our naval strategists nt Washington cause for serious refie

Gun for run, armor for armor, a "Rongo" with an advantage of over 50 per cent in sea speed, should prove hore that a match for any of our battlephips saterior to the "Delaware" and "North Dekota;" moreover, the Japanese admiral would not heetate to place these four ships in line for a fleet action, where, atthough they could take more than they could take, the excellent distribution of their nine to ten-inch armor, coupled with the heavy protective builkheeding, would estable them to stand some very heavy punishment. The speed, the extraordinarily wide rapps of action due to their enormous fusi supply, and the great runge and power of their batteries, would make the existence of such a feed, in the weat of bootlittice, a hard out for strategists to crack. They would resider the con-Gun for gun, armor for armor, a "Kongo" with an

vering of troops across the Paritie, specified the little, an other impossibility i and with if of colliers maeting them at points of points a squadron might work haved to our see in any case it is certain that they might below a way burden on the Nevy, through the feats which the would excite of bombardment, and the inevitable is mand which would be made in Congress for the ing of at least a portion of our battleship it

coast-defense duty.

On the other hand, we hear rumors from Gesiat.
Britain that the battle-cruiser type is to be discountinued, or rather, that it is to be merged with the parent battleship in a new type, combining the spised of the one with the high offensive and defensive qualities of the cite of the other.

#### The History We Want to Read

PACE is the child of war. The present generacivilized portion of the earth, a period of quiet and peace such as is perhaps unprecedented in the his-tory of the world. Not that all war has ceased—a look at the newspapers is enough to convince us of the con-trary—but such wars as have been waged within the last forty years or so have not—in the Western World at least—drawn flame and sword through our very rths and homes, have not even disturbed industrial and mercantile pursuits in any very distressing meas-The arts of peace have continued comparatively undisturbed.

Thus a generation has sprung up for whom war and military pursuits are of academic rather than of and animary purposes are of accessive reason with interest. But the writing and tesching of history has lagged behind the general spirit of our time. The scholastic historiau is often still content to recount for us the catastrophes and intrigues which convalsed the nations in their struggle for light and life. For the truly essential factors of human life-industry, commerce, economic conditions, science and art-these "his merce, economic countrions, secrete and art—tiese "mar-torians" have at most a passing reference here and there. But, it may be urged, such topics are reserved for specialists, for works on the history of industry, art, science, and so forth. The retort is: Then the history of wars belongs to the specialist in military science. Surely Ms field is more remote from general interests, at the present day, than that of the manu facturer and merchant. If, therefore, the general his tory written and taught for the benefit of the genera (as it must) from special surely it is more natural that it should select chapters from the history of science, art, and political eco omy, than from the records of war,

We may compare the wars through which a nation passes in the course of its evolution, to the sicknesses with which an individual battles on his way through life. What would we say of the author who should write the biography of some great man, and content himself with an account of his struggles with the measies, croup, and other allments which he sucfully encountered, until at last the grim enemy won his accustomed victory? Such an account might indeed be of interest to a specialist—to the medical practitioner.
To any other person it would appear nausoating. But this is precisely what the average historian does in re-lating the life history of nations. One would almost think that war was the chief end of human existence!

And there are so many things which we, the reading public in the twentieth century, would like to know from the historian. When did men begin to mine coal? When and how did money come into general use? How much gold has been in circulation in the several civilneed countries of the past, and how have the figures changed, and what are they now? To-day the population of the United States is about ninety-one million that of Germany sixty-five millions, of the Brit ish Isles forty-five militons, of France thirty-nine milions. But how did they stand relatively ten, twenty, thirty years ago? Who would agr that this is a matter of indifference to the nations concerned?

But above all, let not history be a mere narrative,

But above all, let not history be a mere narrative, a collection of peetly stories and romantic advantuses—though romanice has its place in history—but let us have a sober account of the history of maching, more nor less than a natural phenomenon, Let not history be presented as a series of causally disconnected events, determined by the captice of faupred individuals, but as an orderly sequence of steps da a process of evolution governed by the inscoreable laws of

Round the World in Thirty-six Days.—Dy making the elevant of the world in 95 days 21 binns and 85 minus 1. 31. Mars, approximating the New York Seviney See, has reduced the record by nearly foun days below that made by A. Jaques-Schoold in 1931. This medical back the seventh of the service operation of the various renaphoration compution, who by means of special relative addressived, to reduce delays due to unavailable needless.

Tomace in Terranea.—The grand sortal of canal occacione in July 188 was 200,393,399 cubbe yards, leaving to be converted 1.632,209 cubbe yards, leaving to be converted 1.632,209 cubb yards, leaving converted to compared with 2,259,770 cubbe yards for the converted possible month last year,

Correspondent to the control of the control of the control of the resent article in the Schwertze America on the growth of electrical refuling of steel, we note that automobile simulficiences are availing themselves of the new process for the production of mild-steel castings. One of the largest English automobile maintenances has intalled an electric furnace for supplying contains of this kind for machines made at his factory.

coatines of tas into for mannina mano at instructy.

The frea Mining Industry.—Statistics for the year
1900 issued by the Department of Commerce show
that there were 458 iron mines in the United States,
employing 65,176 persons, and conting for operation
and development \$74,071,380. The production of iron
ove in crude form was \$1,047,129 tons, and its value
at the mine was \$10,053,974.

Appraisal of Our Refireads.—The Interstate Commerce Commission have presented figures to the House Appropriation Sub-committees showing that a carefully worked out estimate places the cost of field work for appraising the value of the railroads in the United States at nearly \$2,000,000 per year, and as the work will county from five to seven years, the total cost will be from \$10,000,000 to \$14,000,000.

Final Conal Dredging Operations at Panama.—The various dredging units in the canal service at Panama are to be consolidated with beadquarters at Panama. The final work at Panama will be done by the two large hydrasid dredges which are noaring completion. The fuel supply for these dredges will be brought from the Atlantie and of the canal in barges, and the fuel oil will be plyed into a task at Panaiso.

Widening a Tube Railway.—The City and South London Tube Railway, the first of its kind to be built in London, is to be widened. Its present width is 10 feet 2 inches, and under the sebeme of reconstruction this is to be extended to a width sufficient to accommodate cars of the same size as those that use other and later tabe railways. These tubes are casal-iron lined, and their enlargement will call for some interestnar reconstruction work.

An Advantage of Railroad Electrification.—An inddental advantage of the use of electric traction on railroads has developed in the freight yard of the New York, New Haven & Hartford Railroad at the Hariem River, New York. The abolition of steam locomotives has so reduced the noise and smoke that land in the vicinity is now being covered with dwelling houses, which formerly was considered, because of these missances, to be uninhabitable.

The Increased Sites of Destroyers.—That there is a steady growth in the size and the power of the destroyer is evidenced by the dimensions of the latest totate of this type which are to be built for the United States Navy. They will have a length of 310 feet, a beam of 29 feet 10 inches, a draft of 9 feet 3 inches and a dimensional to 1,000 tons, with a speed of 294 kinotes. Indidentally, there will be a great increase in the cost. Bids for six ressels of this type vary from \$859,000 to \$694,500 for a single vessel.

Ship's Rudder with a Doorway.—The new Cunard hore "Aquitania," which is about the same size as the "Imperstor." is provided with a novel feature in her balanced rudder. This consists of a doorway leading to the interior of the rudder, which is of sufficient is odd and two when at any time it should become necessary to remove the pin which connects the rudder to the ship. According to the Shipping World, this pin is four feet in length and is larger than the heaviest Projectile made for modern artiller.

projection made for modorn arninery. Completing the Work's Ocean Survey.—That the work of charting the rooks' and shoals which constitute a meanes to navigation is not by any means completed is shown by the report of the Navy Hydrographer of the British Admirally for 1912, in which he states that during the year no less than 509 rooks and shoals were reported. Of this total, 10 were reported by navial vessels, 120 by surveying ships, 0 were found by ressule striking upon them, 50 were reported by avoice British and foreign authorities, and 311 were reported by volential and foreign authorities, and 311 were reported by volential and foreign governments.

colonial and foreign governments.

Suffragette Vandalism at an Observatory.—A suffragette bomb (this time a real one) was exploded on May 21st under the west dome of the Royal Observatory. Edinburgh, in immediate proximity to the 24-inch refeces and other instruments. Only the strong floor of the dome prevented serious damage from being done.

come prevented across a content of the content of t

The International Association of Academies hold its fifth meeting in St. Petersburg the middle of May. At the suggestion of the Berlin Academy a committee was appointed to encourage the organization of valicanological materials in the various countries; ultimately an international to the various countries; ultimately an international to the various countries; and as commercing link between these national bodies. An east commercing link between these national bodies. An extra was appointed to consider the resultility of introducting more scientific scale and definition of compound colors was appointed to consider the resultility of introducting more scientific scale and definition of compound colors of the control of the constitution of the constitution, was a French scheme for reforming the calendar, according to which Easter would fail on a fixed date and any day of the year would always fall on the same day of the week. The association was lavishly entertained, and the delegates were inclinically presented to the Casr. The next meeting will be held three years hence in Bertil.

As International System of Pilot-Balloon Stations is a desideratum to which Prof. Horgesoil, president of the International Commission for Scientific Aeronautics, has recently called attention. A pilot-balloon coarries no basic or apparatus of any kind; it is simply set adult, and its motion through the air is followed with a theodolile. It thus serves to determine the direction and force of the wind at different levels. In Germany these are upward of fifteen stations at which such observations are made every morning, and Prof. Hergesedl urges that other countries establish a corresponding number, in proportion to the extent of their territories. The realization of these projects would be not only of great theoretical interest to meleonogists, but since of much practical value to accronauts. It is understood that about fifty such stations will be established in Russia within the next two years.

The Expedition to Easter Island initiated by Mr. Scoresly Routledge, brief mention of which was made in the Scientric Amazarax of Reptember 21st, 1912, page 239, sailed from Palmouth, England, on Marsh 22th. An previously stated, it to object is to study the remarkable stone statues and other remains of an unknown people on this mid-Paelife Island. As there is no regular communication with the island, the party goes in a small yacht, chattered for the purpose, and all subsequently make a cruss among the less-known islands of the South Paedite. The expedition is under the ausgioes of the British Museum and the British by a great from the Royal Society, and is promised by a great from the Royal Society, and is promised urrher assistance on the part of the Chilean government and the proprietors of Easter Island. The party complete, besides Mr. and Mrs. Routledge, Mr. O. C. S. Crawford, of Oxford; Lieut. D. R. Ritchie, R.N.; and Mr. F. Lowyr-Corry, of Cambridge.

A Change in Department of Articulture Publicationa—
The Scoretary of Agriculture has announced a new plan
of publication work for his department. The old independent sories of buildins and circulars of the direct
publishing burseus, divisions and offices of the department have been discontinued and will be superveded
by a new Journal of Research for printing scientific
and technical matter, and by a department series of
buildins, written in popular language for selected and
general distribution. By this plan the confusion that
has resulted from the multiplicity of series of publications will be avoided, and the swring of a considerable
sum will annually be effected. Under the new plan
tha department will discontinue the general distribution of matter to scientific or technical is to be of little
or no use to the lay reader. It will supply bechained
information only to those directly interested and capable
of using scientific analyses, and of understanding the
results of research work couched its obesidité terna.
A larger amount of information, is popular form which
the average resider and muchanished productive or wide
the advantage, and thereby increase the agricultural
productiveness and the health of the nation, will hereafter be distributed.

Heating the Steering-wheel Rim.—To avoid the difficulties resulting from a cold-steering wheel, Rueben S. Smith of Marshall, Toxas, in a patent, No. 1,062,745, arranges an electric heater of a special construction described in the patent, in the hollow rim of the handle wheel, so that the rim will be heated electrically.

Two Patents to Howard E. Coffin.—Howard E. Coffin of Detroit, Mich., has secured two patents, Nos. 1,060,-819 and 1,060,820, relating to starting devices for explosion engines in which compressed air is utilized by a novel valve arrangement in securing the automatic starting of the enrine.

Heed Lamps That Shift Automatically.—In a patent, No. 1,063,962, Charles C. Bruff of Cualport, England, mounts the head lamps of automobiles with vertical reflectors which can be rotated in front of the lamps and are automatically and simultaneously rotated in accordance with the turning of the automobile so that the beam of light from each lamp is divided and an area is illuminated which extends both directly in front of the vehicle and in the direction in which the vehicle is being turned.

A Bell That Sings When the Tire is Defiated.—Hermann Jacoby of Eberstadt, near Darmstadt, Germany, in a patent, No. 1,062,567, shows in connection with a pneumatic tire, a bell and a spring actuated sounds therefore, normally clear of the bell, and having a portion projecting relatively near to the ground surface and alongside the tire, so that any unusual defaults of the tire will cause the said part to strike the ground and result in a sounding of the bell.

A Novel Asti-akid Device.—A patent, No. 1,062,018, has been issued to Thomas Townend of Winnepog, Manitoba, for an attachment to automobile wheels wherein it is sought to grevent the wheel from skidding or slide advense by providing a series of spring-controlled dogs or claws which may be depressed to engage the ground surface, an adjustable wheel being provided to depress the dogs to a position beyond the erreumference of the tire at the under side of the wheel as the latter rotate.

A Novel Wheel Rim.—Victor Lindholm of Hoquiam, Wash, has patented, No. 1,053,888, a wheel rm, unsuffange of which has an entrance opening, which can be closed by suitable means provided for that purpose. The tire is composed of a series of sections of wire rependesed in a rubber casing and bent longitudinally to enclosed in a rubber ossing and bent longitudinally conform with a conventional ure with the sections helded at their ends in tubes wheel can be slipped through their at their ends in tubes wheel can be slipped through their suitable position, so that the tire will be emposed of a number of these sections resting side by side and extending the sections are suitable positions.

Bealten of Brakes to Car Weight.—In the May 10th issue of the SERNIPIC AMERICA, there was published an item on Brake Capacity and Efficiency. The statement, attributed to Prof. C. B. Veal, of Purduc University, that brakes should be designed with one square inno do braking surface to every tem pounds of car weight, should have been given as one square innet to every fifteen pounds of gross ear weight. In pointing on the error me this item Prof. Veal informs us that the coefficient of friction will be determined by the kind of maternal and finish employed in the brake drum and in the liming: and that this coefficient, the heat and wear resuting qualities, design of the brake, as well as the relation of the peripheral velocity of the road wheel to that of the brake drum, all have a direct bearing upon the amount of brake surface required. In general practice the relation of wheel diameter to brake drum diameter varies between 2½ to 1 and 2½ to 1 for pleasure cars, while for a loaded truck this ratio may run as low as 1.8 to 1. In the latter case the amount of brake surface per unit of weight may be reduced by one half the above value for pleasure overs. In both pleasure and commercial velicies, in the contract of the pleasure overs. In both pleasure and commercial velicies, in the contract of the pleasure overs. In both pleasure and commercial velicies, in the contract of the pleasure overs. In both pleasure over under the decided of the peace that the above value for pleasure overs. In both pleasure and commercial velicies, in the contract of the pleasure overs. In both pleasure and commercial velicies, in the contract of the pleasure overs. In both pleasure overs in the profession to the increase in brake-drum velocity, since oving to the mechanical advantage gained in the peace reduction the same retarding effect can be sourced with less braking effect.

### An Integrating Opacimeter for Stellar Photography By Jacques Boyer JULES BAILLAUD has pro

ted before the M. Academy of Sciences of Paris an opacimeter ers in which will render valuable service to astrono the study of stellar photographs. The opacimeter

which is now most extensively employed in astronomical observations Hartmann's microphotometer, which, though excellent in its way. does not appear to satisfy all demands completely This instrument produces, by means of microscope objectives of high magnifying power, real images of the photographic ity from one end to the other. The grain of the silver deposit is seen in both images, and the measurement consists practically in comparing the distinction of the grain in the of the scale comparable with the star image. Hence the scale must star image reene grain as the star plate, and it must therefore be changed for each new emulsion and

Another requirement, still more important and more difficult to realize, is that the star images must be perfectly homogeneous. This is never the case with extra-focal images; those formed by modern lustru-ments do not show visible wings. but they are more transparent at the center than at the edge Schwarzchild has overcome the dif-ficulty with his "Schradiercassette," but this is an ex-

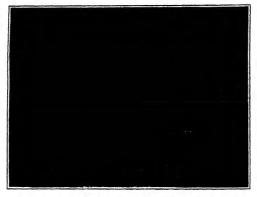

tremely complicated apparatus, and it cannot be used some kinds of astronomical work. For example, would prevent the simultaneous employment of photographic equatorial and a telescope of short

It seems preferable to adopt an optical system and logous to that of the Gouy spectrophotometer. This has been done in the Baillaud opacimeter, a plan of which is shown in the accompanying diagram

In Baillaud's justrument, as in Hartmann's, the star plate B is compared with the scale E with the ald of two telescopes, I and II, and a Lummer and Brothun double prism P, which is cemented together and forms a cube. The central part of the diagonal surface is clear, and transmits light from the telescope I, whose onter parts are silvered, and reflects light from the telescope II in the present instrument, however, the two objectives L L' are focused on the plate B and the scale E, so that the prisms are traversed by pencilthe scale S, so that the prisms are traversed by penculs of parallel rays. A leas L receives both penculs, and forms superposed images of the plate and the scale in the plane of the cychole O. The eye pisced behind this aperture receives the whole of both luminous pencils and, looking at the lens L, compares the illuminaed by the rays tion of the central spot, produc from the star plate, with the illumination of the surrounding annular zone, produced by the rays co from the standard scale, and reflected on the double

The region of the plate under observation is the are whose image is bounded by the eyehole. This area is inversely proportional to the magnifying power of the optical system  $L.L_{ii}$  which, in turn, is proportional to the ratio of the focal lengths of the two lenses. Each of the telescopes I and II, which are exactly alike, is

respectively. The advantages possessed by the are Bailland opacimeter (a duplicate of which has been in stalled in the observatory of Buch very evident. In the first place, it is possible to a with this instrument the aggregate transpare any part of a plate lacking in uniformity.

#### Cathode Rays from In descent Lamps

By Our Berlin Corresp

WHEN a curbon filement femo is operated at a tensi normal (for instance, a 60-volt lamp at 75 volts) a bluish glow is sometimes seen to fill the whole bulb, which, in the spectroscope, shows the lines of mercury. This glow, on account of the gas give out by the bulb or the filement, w w111 disappear again after two to three minutes. On approaching a horsewhose the income through the income incom

en recently investigated by Prof. L. Houllevigue of Marse versity, are evidently due to the electrons given out from the carbon filaments, and which by striking the residual mercury vapor in the will render this luminous.

When glass reservoirs of differ-ent forms are cemented to the bulb and the apparatus is connected with

and the apparatus is connected with a Gaede air pump, the glow is seen to penetrate into the reservoir to a distance that increases with the vacuum and the heat of the filament. If in the apparatus are inserted electrodes kent at different u, the glow is seen to behave like a gase negatively charged in bulk, that is to say, it is attracted by positive and repelled by negative charges. The effect of a magnetic field is not very marked; while the glow is seen to contract, no lateral deflection, in acc ance with the laws of electro-magnetism, is obs

These phenomena seem to suggest that the glow is due to electrons sent out from the negative end of the filament, which after traversing complicated paths in the interior of the reservoir, return to the positive end.

Interesting phenomena are also obtained with an arrangement similar to that used for the production of canal rays (Fig. 2). An incandescent built A is connected with the reservoir B by a tube T which contains either a platinum coil or a hollow platinum cylinder raised to a higher potential than the filament; this is how an electrical "acceleration" field, adjustable at will, is established between T and the filament. Under e circumstances the same diffuse lumines before is obtained in the reservoir B, provided the vacuum be sufficient, except that it contains a considerably brighter beam of rays with accurately defined The same phenom lamp worked at normal tension, but it is altered dis tinctly by any slight variation in the operation

A characteristic feature of the rays is their extra-ordinary sensitiveness to the action of magnets, even the terrestrial field being sufficient to produce an ap-

From the experiments made with these rays it is concluded that they are real cathode rays of compar-tively low speed, say about 5,000 kilometers per secon

nt lamp giving out slow cathode rays,

Fig. 2.—An arrangement similar to that used for production of canal rays.

Pig. 3. -0

There is the of Castlers as a fuel manager of the state o white-on one or more of the atlanting neavier pild seem that much has already been ac-along this line, since the Standard Oil Com-by assessment that it had brought out a new "motor spirit," which takes the place of

rust withing "matter spirit." which takes the place of gasolies, say in some inhances gives even more power than the says quantity of gasoline.

On the chier hand, great advancement has taken piece in the development of apparets to increase the power derived from existing fuels such as keroseou, aschold, distillates and heavy oils. This was clearly and convincingly demonstrated in a recent test in New York city of the G. O. vaporise which has been introduced into this country by an English firm. This vaporise takes the place of the minifer on the vahicle and recentles it in appearance. It is constructed in such a manner that the fuel, in being drawn through at, is subjected to the heat of cast from socumitations which are kept at a high temperature by the

through it, in subjected to the heat of cast from accum-intoths which are kept at a high temperature by the arhitust; gases. Thus the twel is vaporised before it reaches the carbureter and is in proper condition to be mixed with outside air to form the explosive mixture.

the test mentioned several different fo in the test members everal uncertaintees were tried. These included gaseline, kerosene, denatured alcohol, heavy oil distillate and a refined pine wood dis-trilate having the nature of turpentine. With the enrunning at 1,500 revolutions per minute, 66 horses was obtained with gasoline when operating entry with the carbureter. With the vaporier switched is between the fuel supply and the carbureter, the horse power derived from gasoline, at the same motor speed, was 67; with keroseas, 67; with the turpontine spirit, 67.2; with distillate, 68.5; and with alcohol, 61. The consumption of gasoline with the carbureter was 0.8 of a pound per horse-power per hour, while this figure was to 0.7 with the introduction of the vaporiser,

responseting a saving of 12% per cent.

The following table shows the exhaust gas analysis at two different speeds of the motor, first with the carbureter and then with the vaporiser:

#### EXHAUST GAS ANALYSIS.

	-With	carburetet-	~With	vaporiser-
Speed	1,200	1,600	1,200	1,600
CO,	9.6%	7.4%	12.0%	10.2%
co	1.5%	3.2%	0.6%	2.8%
0	2.2%	4.3%	0.4%	0.8%

The temperature at which the fuel is mixed with air in the vaporiser varies between 550 and 750 deg. Fahr. A certain amount of air passes into the vaporiser and is raised to this temperature, although the mixture is reduced to a temperature of about 122 deg. Fahr. on being mixed with additional air in the carbureter.

#### poving Carbon Deposit with Oxygen

CARBON deposit in the cylinders and valves of in-ternal combustion engines has always been one of the great disadvantages of this class of motive power. This is emphasized more strongly in the automobile Thus is emphasized more stringly in the automobile motor than in any other type of engine on account of the frequency with which it is found necessary to take down the cylinders and remove the valves for the pur-pose of getting rid of the carbon deposit.

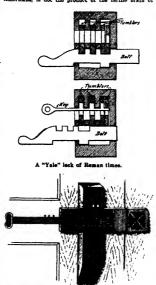

ever, the motorist may now rejoice, sw quick and easy method has been found by means of which the worst car-bon deposit may be cleaned out of the engine in a few minutes without the necessity of taking down the motor or re-moving the valves. The device is known as the Dy-Karbo, and is shown in opera-tion in the accompanying Blustration.

as the 17-k aroo, that is shown in observation in the accompanying illustration.
The outsit consists of a tank of exyrcu gas, a speaking wide of a tank of exyrcu gas, a speaking wide of a tank of exyrcu gas, a speaking wide of a tank of exyrcu gas, a speaking wide of a tank of expensive base and at a tercah. Out the end of the storch has a final-tile copying tales out gastl bore and of the force has a final-tile copying tales out gastl bore, and the storch has a final-tile copying tale of the storch has a final-tile copying tale of the storch has a final-tile copying the similar copying condition units of a speak of the storch distribution of the storch distrib

fect the instant the crimders and valves are clean. The process affects only the carbon and does not attack the metal of the cylinders. In a cylinder where the carbon deposit is extremely heavy, only a few minu required to burn all of the deposit away.

#### The Prototype of the Yale Lock By Walter Schumann

N OT long since I had opportunity to discover that the principle of the Yale lock, so well known to Americans, is not the product of the fertile brain of

Egyptian pin-type lock invented of sand years ago.

s, as I had hitherto always ised, but that it was known to ancient Romaand was in use by them, as early as the beginning of the Christian era, if not before.

Far up among the Taunus Hills, about half an hour's trolley ride from the well-known German spa of Homburg, the erstwhile favorite watering place of the late King Edward VII. of England, on a commanding hilltop, is an old Roman outpost that was destroyed by the barbarians. Of late years, however, and at the instance of archeologists, the site of this outpost has been thoroughly investigated, the ruins laid bare, and on the original foundations the walls of the outworks as well as the inner buildings have been reconstructed rding to Roman tradition

Among the many articles of use and ornament discovered in the course of the excavations, all of which are exhibited in one of the reconstructed buildings, the thing that interested me most was the style of lock that had been in use by these Romans. It is built precisely on the principles of the modern Yale cylinder lock with its tumblers and serrated key. I procured a replica of one of these locks (there were a number of a, each with a different combination of tumblers) and I herewith submit a drawing of it.

One of the drawings shows the lock closed and the key withdrawn. It will be noticed that the four tumblers have dropped into the serrations of the bolt and securely hold it to place, preventing it from being slipped back. The other drawing shows the key in-serted in the slot, the tumblers raised, and the bold situped back.

A glance is sufficient to note that the lock is built on the same principle as the modern Yale cylinder lock , the only difference being that in the Roman lock th key, after being inserted in the slot, is lifted upward in order to raise the tumblers, and that the bolt is then slipped back with the other hand; whereus, in the Yale lock the key is turned and not only lifts the tumblers, but at the same time releases the bolt.

It is perfectly evident, however, that the principle is the same in both locks, and little do we think, as we slip the little serrated key into the lock when we enter our home, that the ancient Romans unbolted the doors to their houses in practically the same way

[A much older lock employing the "Yale" principle was described in the SCHENTIFIC AMERICAN of Scotem ber 2nd, 1890 The lock, as shown in the accompany-ing drawing, is of the pin type and was used some 4,000 years ago in Egypt Similar locks are still to be seen in some of the older streets of Cairo—Editor |

#### The Inventors' Guild and the Oldfield Bill

A T a meeting of the Inventors' Guild, held in New York city, on May 28th, resolutions were adopted in which the Oldfield bill was strongly condemned. 1 n solutions an invitation is extended to the Chamhers of Commerce in the principal cities of the United States and similar representative organizations to aid the Gulld in its efforts to secure the appointment of a special commission, which will make a thorough and careful study of the American patent situation and then recommend to Congress such changes as may appear It will be remembered that in 1911, the Guild petitioned President Taft to have such a commission appointed President Taft responded by sending a special message to Congress on the putent system ich the recommendations of the Guild were in

dorsed. Congress did absolutely nothing in the matter.

There is reason to believe that President Wilson is not indifferent to the faults of our patent system. In his "New Freedom," he comments upon the difficulty many inventors now experience in "resping the full rruits of their ingenuity and industry," and he states that "one of the reforms waiting to be undertaken is a revision of our patent laws."

But whether or not the President will of his own

initiative arge upon Congress the necessity of patent reform, there can be no doubt that if the present plan of the Inventors' Gulld is carried out, Congress cannot remain in-different. The Chambers of Commerce of our large American cities, representing us they do the industrial interests of thousauds, dependent upon absolute justice and fairness in the granting and upholding of natent rights cannot be broared. So far as we are aware, the Cleveland Cha her of Commerce is the only body of this aracter which has considered the puter situation at all. Indeed, its admirable. critical study of the Oldfield bill, and its report on the patent system of the United States, notedated and probably hispired the present resolutions of the Inventors' Guild. If the example of the Cleveland er of Commerce were followed, who can doubt that Congress would be induced to appoint a commission which thoroughly study the natent system and which would result in the enactment of the kind of legislation that would meet with the approval of inventors, manufac

For years business men have pointed out the need of a new Patent Office building, a simpler and more efficient system of Patent Office administration, and readier means of bringing infringers of patent to book, but Congress does nothing

### Comparison of French and German Strength in Dirigible Airships

#### Why Germany is the Leading Air Power

I N a recent number of La Nature, there appears a critical estimate of the relative all strength of Germany and France. Insemuch as these two powers have been keen rivals in attaining what may be called a supremacy of the fit, an abstract of our French contemporary's article will doubtless prove of interest to

As regards the French dirigibles, the three most recent nerial cruisers, as well as the largest (8,000 cubic meters), finited (5 kilometers per lour), and the best equipped, are the "Adjudant-Vincenot," located at Toni: the "Adjudant-Reau," at Verbus; and the "Duppy-deloues," at Manleuge. To these should be added the "Pileurus," which exceeds them in speed (58 kilometers

"Figures," which accesses the an hour), but has not as great a gas capacity (6,500 cuble meters). On the first three engines of 200 to 250 to

The table lists the French dirighties which have notually been hullt, including privately owned craft, which can be commandered in time of war. The names of these are given in Italies.

Most of the Freuch dritalines are of the flexible or
non-rigid 13 pe (8). Hetween 180s and 1011 Franceball four sensity completed
(8). The rescuity completed
(8)-prison," a wood-frame
dirigitio, marks the entrance
of France into the field of
rigid dirigitios (IL.) litherto dominated by Germans. On the other hand, it should be noted that one of the flexthic types, the triboled type
invented by the Spanish engineer, Torreso Quevedo, and
built in France by the Astra
Company, presents advantages nanologous to those of
the rigida, because of this
means adopted to preserve
the shape of the envelope
under varying conditions of
temporature and gas pres-

Such as it is, our French contemporary admits that the French fleet of aerial crutaers is interfor in number, gas expactly, speed, and radius of action to the German The difference is even greater than shown in Table 1, for Lo Marier has sibuliated only the best French airbilips, vessel is wit if he would be immediately available in case of war. Most of the others are either betting repaired or remodeled. For example, the new "Spless" rigid will be available only

niter a long period of testing.
By the end of 1013 the
French military neconautic
authorities will surely have
put in nervice neven intremilitary dirighties of 20,000
cubic meters gas a capacity
and a speed of 75 kilometers
an hour. The four large airship manufacturers (Bayard-Glement, Astru, Zodies,
and Lebaudy) expect to construct four large privatelyowned cruisers as well as
four other dirighties of the

Military dirigibles of over 8 000 cubic meters gas capacity are called oraters gratose of 5,000 to 5,000 souts, and the smallest, redeties. "Fleuras" type, which will be built by the first three of the above-meutioned firms. Hence, taking account of delays, etc., by the end of this year France may have a dozen large dirigibles actually in service, though these will be interfer to the large German cruisers.

Germany's dirightle strength is shown in Table II. What strikes us at once is the large number of stidd cruisers and their gas capacity, speed, and radius of action. We may add that the available lead they are capable of carrying surpasses the tons for the large Zepyelins ("Victoria-Labe," "Hansa," "ZS") and six tons for the latest marine dirightle.

In the table the Zeppelins are indicated by the letter Z (or L for the marine dirigible), the Parsevals by

P or PL, the Ruthenbergs by R. La Nature omits the three (frees military semi-rigids formerly designated by the letter M. One of these, after being regulated, will be stationed at Mets. Notifier has In Nature included "Ad," which figured in the Lunwillé incident. "PLO" and "PLO" are out of service.

This talle does not pretend to be complete, nor evan to be very exact, since changes in aeronautic organization, as well as in the stations of airchips, are frequent and secret. Thus the names of the stations must be considered merely as an indication. "23," for instance, indicated as attaches to Pherlin, is really said to be destined for Metz. Likewise it is impossible to know from day to day which craft are in commission. But

rart are in commission. Set the list reproduced from Lo Nature suffices to show that Germany does not possesse forty Zeppelins, as the European press has frequently asserted.

Though only one Suchard is given in the table, there is a second Nuchard, which is a necessary of the such as a second Such as the city of the table the command of Capt. Hruncker, was intended to vayage from Lass Palmas (Camir, Islands) to the West Indies. As for the Parseuril type, its gas capacity is 12,300 cmbic meters with it car 10 meters long und a 200 hove-power earlier and a 200 hove-power earlier.

While it is impossible to state definitely to which sirship harbors German dirighter are attached, it is certain that they can be housed in eighteen slicks of the fixed or tunnible type. These sheds are situated at Berlin, Bleedorf, Potedam, Königsberg, Posen, Kiel, Hamburg, Dissedorf, Leich hil ngen, Chingne, Meta, Frankfurt, Mambletin, Beden, Sirussburg, Gotha, and Friedrichshafen.

It is perhaps the privatelyneued dirichles ("Victoria-Ladae" and "Hanse") which are the usoft dangerous. They are or will be completely armed. The narine "11" even carries a machine gun It is to be particularly noted that the Germans have seriously stided not only the character of weapons, but also methods of firing. The crews of dirighties are trained in target practice to hit objects on the

All the dirigibles except the Parsevals are equipped to send or receive vireless messages. In the five facincies (at Munich, Friedrichshafen, Mannheim, Berlin, and Bitterrick) new sints are sit present in course of construction, of which six are pivestaj-owned dirigibles (one Zeppelin and five Parsevalis).

#### Extending the Law of Unfair Competition

To the Editor of the SCIENTIFIC AMERICAN:

The "Sanatogen" decision is in keeping with public centiment on the matter of the right of a manufacturer to fix the retail selling price on patented articles, and of recent years court decisions are apparently greatly influenced by public demand. There about do to making the court of the cou Federal law governing unfair competition, so as to enable all manufacturers of any advertised or trade-marked an manuscourers or any adversion or crans-marked article, patented or unpatented, to maintain a uniform retail price thereon. Where price cutting is permitted, the tendency is to place the small retailer in a position re it is impo sible for him to compete with his larger competitors.

Measure you of the approval of this company with the efforts of the Surentino American to further the cause of merchandising in a manner profitable to all dealers, manufacturers, and the general public

AMBRICAN THERMOS BOTTLE COMPANY WILLIAM B. WALKER, President.

#### Cast Steel Ties and Screw Spikes

To the Editor of the SCIENTIFIC AMBRICAN:

A most interesting article appeared in the issue of June 7th, 1913, on "Borow Spikes;" you also speak of the antiquated practice of American railroad builders; also of the tie plates outting into the surface of the wooden ties. I inclose herewith a out of a seriew spike, which I have found very useful in connection with cast steel ties which were man-

with easy steel the which were man-infactured several years ago and placed into the tracks of the Le-high and New England Railroad, where they have been in service since, also an insulated oset steel to which is in service on the Lehigh Valley Railroad.

se ties combine tie and tie plate, are elastic, light, strong, and would wear indefinitely. The screw spikes are fastened into blocks or some other substance used for that purpose, for which receptacles have been provided at each end of the tie. The blocks or other material can be replaced without moving the tie, so that neither ballast need be removed nor service of the track impaired while repairs are being

On an electric road they are a most valuable asset, since repairs on city stree would be reduced to the smallest minimum. The ca street would be reduced to the smallest minimum. The cast steel it is preferable to any rolled device, since the latter require bolts and elips, which are a continual appears and dangerous, while some uplies are used with cast steel ties, thereby insuring safety. The accompanying photographs show two of the ties in position, also a server spike.

Bethleben, Pa. MILTON M. MITMAN.

#### How the Consumer is Affected

To the Editor of the SCIENTIFIC AMERICAN:

the Sciitor of the Scientific American; rice cutting does not lower the coat to the con-ser. It can only lower the quality to the con-er. Price cutting, in encouraging and necessitat-the lowering of quality, works injury to the consumer. ing the er. distributor and producer.

Modern competition comprehends price, quality and service. If competition must depend on price since, both quality and service must suffer. Advertised trade-marked goods are sold at the least expense to trade-marker gloos are soir at the less appears the consumer because advertising is the most communal form of salesmanship when properly performed. If the manufacturer cannot legally fix, his own selling price, he has no foundation upon which to build his

gradity and his service to the consumer.

Everything is made or done with the consumer in view. The consumer benefits or suffers in ratio to the ability and prespectity of the various distributors and producers.

the shifty and prespectly of the various distributors and producers.

The producers and distributor must be paid for their severies to the consistence just as the consumer is paid for the service he renders in his particular line of endeavor. Therefore, the price of every settless same include a profit to pay the producer and distributor for wheir work.

Thrifts pressessingly composition, also prices, of an article state to resiscensitely. If the protoc is not resemble, and if it is involved only the producer and the prices of the protoc in the prices, of the protoc is not resemble, and if it is involved only the protoc is not resemble, and if it is involved only the protoc is not resemble, and if it is involved only the prices of the protoc in the prices of the prices of the protocol protocol

salish manufacturer, having an article of equal quality, will sell his goods at a legitimate price that includes no excosses, and, therefore, will secure the business that formerly went to the other manufacturer. Thus, the very lact that any article can remain on the market at a fixed price for any length of time is proof that is is good value. Granted, then, that the prices of such articles include only a fair profit for the distributor and producer. If such a profit is cut, it must follow that either the producer or distributor is not being pad for his work.

for his work.

to nis work.

If continued price cutting so lowers the prestige
of this article that the previous fixed price can no
longer be secured, the cut price will soon become
regarded as its fixed price and the producer and
distributor cannot figure on getting any higher price

distributor cannot figure on government for the goods.

It is, however, obvious that the distributor and producer must be paid. If, therefore, they can only depend on a lower price, they must lower the quality of the goods, so that their profit may be secured even at the reduced price. When such a cut price is established, the consumer really stands a loss through reduction in quality of the article, which

formerly sold at the larger and legitimate price.

Therefore, I believe any legislation aimed toward
eliminating this evil is essential to the good of the
country. It should be instituted as vigorously as
possible.

E. A. STUART.

Seattle, Wash

#### The Law of Magnetic Communications Between Human Beings

the Editor of the SCIENTIFIC AMERICAN: During his lifetime the late Andrew Lang as a ember of the Society for Psychical Research

Combined tie-plate and tie and one of the screw solkes

collected a great deal of valuable data as to comtions received by one person from another ed by vast distances, without the aid of telepraph or telephone.

well recognized that evidence of su It is well recognized that evidence of such com-nucleations must be well afted and weighted, because of the tendency to deception and fakery in dealing with such matters; but allowing for a large percentage of fakery in the evidence secured by Mr. Lang, the residue is of such a reliable nature as to make it reasonable to declare that the truth of such communications is well authenti-

cated.

Now, reasoning from analogy, such communications are not any more wonderful than the communications received over the wireless telegraph. In both instances, the force transmitted is the same -magnetic or electric; nervous energy being elec-trical in its nature, as demonstrated by those who triest in its nature, as demonstrated by those who have studied the nervous system; as shown by the effect of the electrical battery on the human system; of the galvanic energy transmitted through the legs of a frog. While we may trace the manifestations both of electrical and nervous energy, the nature of either force is mysterious and defies

Until Marconi discovered the secret, the law of utilizing electrical vibrations without wires was unknown. His discovery was simple in its nature, as all great discoveries are, i. e., the instrument creating the vibration must be in unison with the instrument receiving it.

instrument receiving it.

With this idea in mind, it will be found that
the incidents adduced by Mr. Lang occurred
between persons who were strongly bound together in unity of sain and thought at the time;
and while he does not impart this detail, they
must have been persons of a vigorous nature,
capable of storing and generating much magnetic ergy.

New, the law dissevered by Mr. Marconi was

not applied practically until some time after he had discovered the principle. I contend that with proper experiments, under the guidance of men of scientific attainment, a method will be found by which communication may be effected, at will, at any time, between human beings separated by great distances. The following, I beliave, is a crude statement of the law governing such communications. munications:

The person sending the message must be one The person sending the massage must be one strongly in unison with the person receiving it, and each human instrument must be a person of a vigorous and magnetic personality.

If this law our by demonstrated in a practical manner, as was Marconi's law, it will be of more manner, as was Marconi's taw, it will be of more importance to human kind than was Kepler's law of planetary motion, because Kepler did not enlarge the usefulness of astronomy by demonstrations of his law, as the epicyde theory of Ptolemy was just as good a working theory as Kepler's; but the practical demonstration of this law of the practical demonstration of this law of the practical demonstration of this law of communication will be of real use humanity. Two adequate magnetic personalities communicating between New York and Philadelphia, or even Chicago and Milwankee, would produce as much of a sensation in the scientific world as did the first successful communications over the

wireless telegraph. Scuddar Richardson.

Houston, Texas.

[The analogy between wireless communication and telepathy is not altogether complete. The wireless telegraph does not transmit thought, but simply signals which can be translated into an intelligible communication. Telepathy, on the other hand, deals with the direct communication of hand, deals with the direct communication of thought. Even the wireless telephone is not a perfect analogue to telepathy; for spoken words are but the equivalent of Morse signals. The

brain must first learn that a correan must meet tearn table seer-tain combination of lotters and sounds such as "water" means a definite thing. In telepathy brain responds directly to brain without the need of interpreting agnals or

We cannot agree with our correspondent that strong personalities are required to conduct telepathic communication. Instances enough to be found in the proceedings of the Psychical Research Societi of America and England as well as in many books which would seem ate that personality, in to indicate that personanty, in the sense in which our correspondent employs that word, has very little to do with psychic phenomena. Indeed, some psychical investigators even hold that we are all possessed

of us have not learned the knack of using them.

To the Editor of the SCIENTIFIC AMERICAN: In view of your editorial on "Research on Leprosy, appearing in the Scientific American of June 14th. appearing in the Scientific American of June 14th, 1913, there is inclosed herewith a copy of Public Health Bulletin No. 47, which contains an article on "The Artificial Cultivation of the Bacillus of Leprosy" On examination of this article, it will be observed that Moses T. Clegg, now of the Leprosy Investigation Station conducted by the Public Health Sovetice Surgeorded in grayment the Insurance healths:

Service, succeeded in growing the leproxy bacillus in 1909, and isolated it in pure culture during the same year. J. W. Kran, Assistant Surgeon General. Treasury Department, Bureau of the Public Health Service, Washington, D. C.

#### The Track Spike Problem

To the Editor of the SCIENTIFIC AMERICAN It is with great interest that I have read the articles relative to spikes for railway use. In your issue of July 5th I note a new idea, namely, that of the barbed spike. It has occurred to me that it would be a very difficult, if not impossible, matter to withdraw those barbed spikes from the ties after "the swelling of the wood by the rain."

It does not seem to me that we ought to say aught against the screw spike because train wreckers might unscrew it from the tie; could not those train wreckers,

with more case and success, use some powerful explosive?
"What goes up must come down," is an old saying.
We can revise that to fit the rail spike and say, "What goes down must come up

From my experience with the screw spike, I think that it answers the purpose better than any of the others. FRED. M. LASE.

Portland, Ore.

## The Japanese Battle-cruiser "Kongo"

#### The Most Powerful Armored Cruiser Afloat

THREE new battle-cruisers are now being built in Lapine—the "Hipte" at Yokoutka dockyard, to Harumi" at Koho, and the "Kirishima" at Nagasaki, while a fourth, the "Konga" has recently been completed by Messra, Vickors, Lid, at Rarrow-in-Purness, and will shortly be delivered. The strategical and factical qualities governing the design of these four battle-cruise, s having been enunciated by the Jay Navy Department from experience gained in the Busse Japanese war, it was left to this firm to embody the stipulated requirements. The machinery for the first of these battle-cruisers has also been constr Messes. Vickers, and she is now in an advanced stage of construction, having been laid down at Yokosuka dock-yard on November 4th, 1911, while the others were laid down in March of the following year. The vessels have the following dimensions: Length, 704 feet; breadth, 92 feet; druft, 27 feet 6 inches; displacen lons; service speed. 28 knots; maximum coal capacity, 4,000 tons, oil fuel capacity, 1,000 tons; shaft horse-power, 70,000; armament, eight 14-inch and sixteen 6-

buch guns; torpedoes, six 21-inch submerged.

It will, therefore, be gathered that the "Kongo" and

her sister ships are practically the same length as the "Princess Royal," but have each 3 feet 6 inches more beam, and 1,000 tons greater displacement, due to the greater fighting qualities laid down by the Japanese authorities The armament of the Japanese cruisers comprises eight 14-inch guns, as compared with an equal number of 13.5-inch guns in the British ship, an equal number (sixteen) of guns for repelling torpedo attack, but e of 6-inch bore as compared with 4-loch in the British ship. The "Kongo" has double the number of submerged torpedo tubes fitted in British ships, and as lu these they are designed to fire 21-luch White head torpedoes. Generally the that in the "Princess Royal," but owing to the introduction of armored bulkhends below the water-line, a greater weight has been absorbed for protection in the Japanese ship

The sight 14-inch come are mounted in pairs in four barbettes, two of which are located forward and two aft, all on the center line. These burbettes are arranged, and the elevation of the gun is fixed, so that four may fire forward and four uft, while all eight may fire ou either broadside. Notwithstanding the very powerful armament provided, the armored protection is most effective, particularly against tor pedo uttack The main broadside

armor is of special quality steel, and is equal in thick ness to that of any battle-cruiser yet designed, and is carried to the height of the boat deck, which is conthused on the same level as the forecastle, forming a citadel, into which the 6-inch gun casemates are worked. The male belt extends considerably below the waterline, and under this ugain there is an anxiliary armor belt extending some distance below the normal There is a special arrangem ormored buikhends protecting the vital parts of the ship; the magazines, for instance, being co rounded with special steel armor. There is an armored deck at the waterline level, and in addition to this there is an armored deck closing in the ship from stem to stern at the level of the top of the side armor

The water-tube boilers burn oil fuel as well as coal. the turblues are of the combined impulse and reacti-To insure safety, the bollers are arranged in eight compartments, four on each side of a center line bulkhead which extends throughout their cutire length. while the coal bunkers are also disposed to afford pro-tection. Again, the engines—two sets of turbines on four shafts—are arranged in two compartments, with a center line bulkhead between them. The whole of the arrangements preserve the independence of the port and starboard sets of machinery and allow either set worked when all parts of the other are disabled. The high-pressure ahead and astern turbines are of the Parsons combined ampulse and reaction type.

The full power trial of eight hours' duration was car

ried out successfully on May 8th, in stormy weather, a gale blowing most of the time. The de and the speed of 28 knots were exceeded. The designed por

and the speed of 28 knots were exceeded.

The gun triais took place on May 14th and 18th.

The gun-mountings are of the Vickers hydraulic type, The gui-mountings are of the victors advantactype, but have electric gear for use in the event of the bydraulic system in any way failing. In addition, too, there is a small hydraulic installation for working the guns when they have to be cleaned; but this gear will also serve, instead of manual work, for maneuvering the guns in the event of the main supply of power, either hydrautic or electric, giving out. Anothe ure of the installation is the application for the first e of the Jauney-Williams gear, which proved mos reliable and exact in controlling the turret movement ng motion or great speed being achieved with equal facility and precision. The most crucial test was the firing of the whole of the 14-inch guns and of all of the 6-inch guns on the starboard beam, making six-The firing was from the co tower and was absolutely instantaneous. It was re-markable that the cascades throws up by the first con-tact with the sea of the 100-pound shot from the 6-inch

The bow cradle, in front of which are the hydraulic rams for starting the ship down

as, suggesting a remarkable uniformity in the trajectory of the guns. The second contact with the water in the case of these shots coincided with the first contact of the 14-inch shots coincided with the first contact of the 14-inch shot, so that it was not then possible to distinguish between the 100-pound shots and the 14,00-pound shots. The salve represented a discharge of something over eight tons of metal, with a collective mustle energy of about 600,000 foot-tons. The effect on the ship was scarcely perceptible, so far as inclination was con-No damage was done to the ship's stre the only damage being to some of the lifeboats, the side planking of which was sprung. The performance was thus in every way an unqualified specess, and after the gun trials the ship proceeded to the anchorage at tireeuck, whence she left for Barrow-in-Furness on the following day, the torpedo trials being carried out on the way The "Kongo" is due to leave Barrow for Japan early in August.

#### The Visibility of Submarines By W. L. Catheart

THE submarine boat passed long age from the ex-perimental stage, and is now a definite and in-portant factor in the equipment of the navies of the world. On Deparable 18, 1812, there were belti, brild-ing, or authorized for the flests of England, Germany, the United States, France, Japan, Bunds, Estry and Austria. a total of 841 septembries, having an aggre-

gate displacement of about 181,000 tons. White the green in the effectiveness of these boats has been rein tively swift, two comparatively recent improvement. virtually doubled their powers of offer to the unvarying accuracy of the groupout complete the location of the ship to be attacked can be observed at a distance of eight miles, and then the book was run fully submerged to the exact point where, after run runy successed to the exact point where the final sight, the torpedo is to be discharged, the effective range of the torpedo itself has be creased to 11,000 yards by the use of turbine e creased to 1,000 yards by inc use of turbune engines having superheating apparatus in the pressure current. With such range and accuracy and with its ability to strike below the armor belt at the very visals of the ship, the deadly power of the submarines, in so far as qualities are concerned, cannot be question

The development of aviation, however, threats The development of aviation, however, threatens to affect injuriously the offensive power of the submarine in its most essential characteristic—invisibility. Since these boats are both relatively slow and unitrasted, they must be submerged when approaching the skip to be attacked, and hence they must depend on submarg-ence for both their invisibility and their invinerability. This submarigence, however, will ap-

parently no longer save th view, for, in future naval actions, all large vessels will carry sero-planes, and the aviator, souring on high, can readily detect the su rine heading, below the surface of the sea, for its quarry. When Bi6riot made the first flight across the English Channel, he saw near the town of Deal two tornedo-boat destroyers followed by a long line of submarines, the latter being fully submerged and invisible at sea level, but clearly discernible to him in his monoplane. If he had been an aerial scout in actual service, he ld at once have reported the m marines by signals or wireless to els which they were about to attack.

Since then, numerous other aviators have had similar experiences. During the review of the British fleet off Spithead last fail, submarines were thus detected by aerial observers; in maneuvers in Chess. peake Bay, our scouting aeroplanes discovered the under-water craft, without the ald of giasses, althou the boats were at a considerable depth below the surface; an Italian aviator in Tripoli saw on the bottom of the bay the charred wreck of the old United States frigate "Philadelphia," which was burned by Decator in 1803, after her capture by the Algerines; and very cently Lieut, Bakoppios of the

centry labelt. Bakopulos of the Greek navy observed on the reefs called Pharos Rank to the eastward of the island of lemnos, at a depth of from five to twenty-five maters, the roins of an ancient city which long ago sank be-

In military aviation, it has been found that a trained observer at a height of one mile can distingu tween troops of the various arms on the earth below, so that so far as clear vision of the scene beneath is no that so har as clear vasion on the receive butterns, we construct concerned, man seems now as capable as the souring eagle or the carrious birds with their dan-placeting game. Further, the eye at these Frest bigints is able & penstrate the mask which, at the surface, hides the depths trate the mask which, at the surface, hides the depths of the son below. There are two reasons for this virtual invisibility of these depths to the unaded, spe of son-level. We see an object by the light resident shown it, and, as the surface of the water reflects much of the light which strikes it, but relatively little page. the light which strikes it, but relatively little some trates below. Hence, the depths are dark as companied with the wuntit air above, Amin, the resteemed light at the surface dambes the eye of the observery and pre-valus it from receiving such rays as six elementaries from a submerged object. Many despois Saison here globalist, profuberant eyes, as shaped at no justice the last ray of dim light about them. To one out surface restertion, spoup shaber looks through the "reace tea-cope," a box without a top and having a place heatens, which they shak about half with place for smaller. The "Differ water gloss," a distribut appairing in its small behavior of the company of the companies. The

of vertical rays is zero. As Section of removed, the spectrum of the observer from prices, the less the light will be reflected and the will be the amount of vertical rays received by.

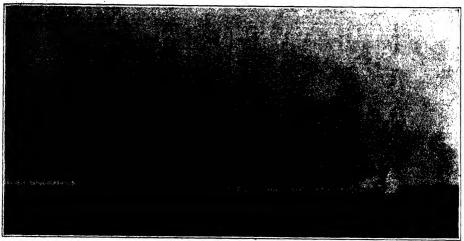

the eya. Again, as has been noted, surface reflection dandes the eye and interferas with the direct rays which otherwise would reach it. By rising to an ait-tude at which the reduced light is virtually sliminated, as detthe case of the acropians, the eye receives only the direct says transmitted from objects besuch the

surface. From these considerations, it seems clear that, in see water of nermal translucency and at its cruising depth in war, the invisibility of the submarine to an aeropiane lovering above it is a thing of the peat, except at night and in loggy weather. These conditions have been recognised fully by naval experts. Last September, Capt. Washington I. Chambers, U. S. N., now in charge pet haval station, in a report on the subject to the Bureau of Navigation, specified, as one of the contem-

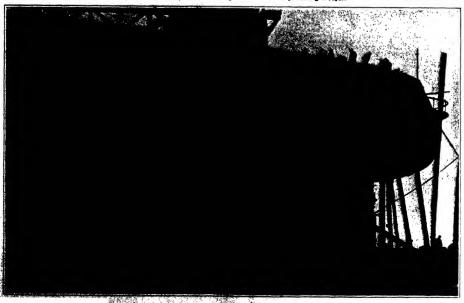

plated uses of aeroplanes in naval warfare, "to locate patted uses or aeropanes in nava; warrare, "to locate and destroy submarine miles, submarines, and dirigibles, and to assist in the operations of submarines and torpedo boats." While the visibility of the submarine miles to an aerial observer is another story, we may mine to an serial observer is another story, we may note in passing that, if Makaroff Snagalin, in its sortie from Port Arthur, had been preceded by a scouting acroplane, the mine which sunk her would have been discovered long before she reached it, and the galiant admiral, his crew of a thousand men, and his great ship would have been saved from the swift destruction which they met.

The fleets of the air seem at present then to be fully capable not only of leading but of attacking, more or less effectively, hostile under-water craft. When it is

#### Boots Ripped by Lightning

The boots shown in the accompanying photograph were worn by Mr. John M Carns of Provincetown, Mass., on June 2nd, 1862, while he was in his boat fashing. A thunderbott struck the man and rendered him uncouncious for several hours. One burn ottended from elbow to wrist. Another burn rau from the neck to a Joint low down upon the back. The worst burn wis on the right leg. The boots that Mr. Carns wore were practically new at the time. The lightning ripped the soles from the upper, fore apart the seams and reduced much of the leather to rags. The victim spent six weeks in the Boston City Hospital, where the doctors offered to cancel his Mill of 800 in exchange for the boots, but the owner prized them too highly and kept them until his death, at the ripe age of 92

#### Belgian Sand-boats

THE introduction of the sand-but has relegated to the rear all other spects at the Belgian sea-side resorts. Whitsing by, at almost the speed of an accopiane, these fragile beats, mounted on four bleycle wheels and displaying a great main-sail, bellied with the strong wind from the North Sea, present a picture of pleasing novely.

The Belgian coast, from the bordaring French town of Dunkirk to Plushing light-house, the first landmark in Holland, is an unbroken stretch of level sangly beach. Lotted at latervals of from two to four miles are Zacabutating resorts, buttle upon the famous said dunes, for which Belgian is so noted From La Panna, Cozyde, Oostenkirk, Nieuport—mil the way to the important city of totends, and still farther on, to the favorite see-side town of Bianksenberghe, these white-winged sand-boats are sent out to compete in the races, up and down the const. As the yield sold sabitas, these contests are of almost daily contributed.

Pleasure-seekers galore gather to choer the boats from their respective reserts. On a fine day, the eather stretch of sauds is an unbroken line of moving humsnity. Children on donkeys, led by contumed personal girk who patter their bare feet over the smooth, wet beach, shell gather-ers and lide strollers—all of thein turn to rinor plantom-like hosts, sweeping alreast on insoft—the pennants of America as well as Reigitum futtering from their masts. Sailing it on a hurricane gale or plowing their way through a sand drift, hurling the glassy particles abidt, as a cloud of spray abeam, the passing of these boats for the signal for a spontaneous cheer that accends and floats away across the sea, only to be echoed back, as a signal of the approaching race, to those persons farther up the strand.

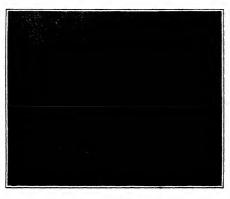

#### Canopied Skylights

I N the south court of the United States A Treessure Building at Washington, D. C., there is a one-story building about 32 feet square, considering of a center parton about 39 feet wide by 92 feet long, and two side wines each 10 feet by the same length. The side buildings have sloping roofs, in each of which are placed three skylights, and a ceiling in which are placed ceiling lights under the skylights, thus formlug air chembers.

Over a large portion of the matu rsom are two "saw-tooth" skylights, which open directly into the room with no celting beneath. There are also two rows of small skylights in the roof over the large room. These small skylights, together with those over the side buildings, are stielded by rolling canvas curtains on the outside, arranged in sections. The tincovered slophing portion of the "saw-teeth" are shielded by fixed canvas curtains over which water is allowed to trickle, the object being to keep the tin roof as cool as possible. These canvas curtains are pinced for enough above the tin to allow a free circulation of air under them and are partially supported by a 3-inch galaxy cantide from play at the ridge of seal sky-vanised from play at the

Havoc wrought by lightning to a pair of boots.

Sand-boat at a Belgian sea-side resort.

Building a boulevard over a sewer

light respectively. The since is acceptant with one row or Alforium those, spaced about a foot apart. The center the through the holes is so set that the jest it water shall strike the naives as high as most the

Thermometric readings taken show that while the beapercture on the argused tin roof outside of the onlyes is, often as high as 128 to 127 degrees, and the beapercture in the dry shade on the issue roof at the same time is 80 to 188 degrees, the temperature of the tin under the wet canusa is zoon 78 to 83 degrees, and the temperature of the room below at breathing line is from Si to 87 degrees, when the temperature of air in the shade at ground level is 80 to 92 degrees.

### A New Copper Photographic

PHOTOGRAPHS upon copper plate are new made by a new process. It has been desired to use the sensitiveness of cuprous salts to light, especially for transg engraving design such images could not be fixed, as reagents dissolve the copper salts, both acted on by light or unaffected, in about the same way. By a new process, a polished copper plate is exposed to chlorine gas for copper plate is exposed to choose gas to a few seconds to produce a sensitive layer, then it is exposed under a negative for ten minutes in sunlight, after which a positive image is seen. The sensitive lay-er should be extremely thin, as a thicker layer is less suitable and is found to be in some cases twenty times less sensitive. Fixing is readily done by a toning-fixing bath containing but little hyposulphite and already charged with silver saits coming from previous use with paper toning. On the plate the affected parts take a brown hue and the rest dissolves out. Other baths can also be used. The image made dagnerrectype.

#### Building a Highway on a Sewer

JONER FALLS, often called the dirtiest sower in America, which has failowed a singleh, devious route through the city of Baltimore ever since it was founded, is being converted into a splendid benievard which affords an easy-grade highway from the outskirts of the city to the harbor's edge. It is called the Fallsway.

Calvin W. Hendrick, chief engineer of the Baltimore Sewerage Commission, conceived the plan, and after a long and disheartening campaign against conjectvative elements in the city, secured the approxiof a million-foliar loan for the improvement. Work was begue immediately. The plans prepared by Mr. Hendrick provided for three conduits, each 20 Seet wide, of concrete, and paved with vitrified brick, to be eracted issivener the relating walls of the stream. Over these a roof was designed, which when coverand with g filling of earth, and paved, would form the street.

The cent conduit was made deeper, and through this the wester will flow under options; conditions. In times of stora, the gates will be opened, and the shool let into the middle phanther. Only in great floods will the third couplet be encountry. Jones Falls has a repetation for disparitous floods, part has frequently overflowed its banks.

nowed its banks. Chief among the many and perplanting problems met to constructing the Fallsway was a great horseeinch good which Air. Hendrick wished to die away with. A tunnel was thereforce efficiel through earlier diversity diversity and the system diverted through it. All the waste hand bordering the hend of the horseebne was thus reclaimed into valuable laint. Out many the borderine of the bitty, the desarted of the street in any fact helms the borderine of the bitty, the desarted of the Spacking of spaints limit. Out many the borderine of the bitty, the desarted of the Spaints of the bitty, the desarted of the Spaints of the borderine of the street, and the street of the desarted of the Spaints of the borderine of the Spaints of the desarted of the Spaints of the Spain

### Inventions New and Interesting

Simple Patent Law: Patent Office News: Notes on Trademarks

#### New Electrolytic Alkali Cell By John B. C. Kershaw

EVERAL years ago Dr. Jean Billiter of Vienna inA-yeated an electrolytic alkali call combining the advantages of the disphragm with the boil gravity type.
Since the patent on this cell was secured, it has been
theroughly bested on a practical industrial scale in
Germany and Austria. At present there are five works
in operation where this cell, known as the Billiter-Sietenses cell, is employed, the most important of these
being the Niaparra Alkali Company. As described in
the patent specification the cell consists of a bell if
(Figs. 1 and 2), which is closed at the bottom by a
disphragm 2. The latter rests on an iron or nicket wireunt 8, which serves as the magnitive electrods. The
boll stands in a vessel 10. In the inside of the bell
is the anode 8, made of pintinum or certon; this is
placed parallel to and at a short distance from the
exthesis wires 8.

In order to permit of a complete separation of the products of electrolysis (wood as pean choicetes), the eef is operated as follows: The bell is filled with the eef is operated as follows: The bell is filled with the eelst object to a predetermined height, while the option of the product of the third works through to the cathods, and forms, there, sodallys. The contest is the product of the lyes in such a position and of such dimensions, that the liquid in the onter ressel just washes the cathods whereast. In order to allow easy sait for the hydrogen bubbles evolved during electrolysis, the cathode wire-not (Fig. 1) may be curred, and may be silowed to abut against impervious channels of having openings allowing the hydrogen to escape easily; or the straight or corrupated exthode wire-not follow sufficient for the purpose. In order to raise its conductivity, the electrolyte may be warmed by a beating pipe, not shown in the drawing, and the apparatus only works well when suitable dispuragus are used. The desired result has been obtained in the Billiter cell ty works well when suitable dispuragus are commercial ashested coloth I (Fig. 1), on which is agreed a special powder displaying 2. According to the invention, a displayment overson, and the surface of continue to the train substance of coloth as from a maximum or beating another or alumina with a substance wood, and this is made into a pleasite, but tenecious and consistent means, with a suitable dispute on a continue means, with a suitable dispute of the means, with a suitable of courter of the means, with a suitable of courter of the means, with a suitable dispute of courter of the means, with a suitable of courter of the means, with a suitable dispute of courter of the means, with a suitable of the means and the suitable dispute of courter of the means and the suitable dispute of courter of the means and the suitable dispute of courter and the means and the suitable dispute of the

mass, with a solution of common sait.

These disphragms are stated to be extremely resistant; they will keep for months or years, and can be quickly and easily changed or renewed, as compared with the ordinary powher disphragms. It is only necessary to remove the layer of mixed sabsetos wool and powder and to substitute a new layer; this can be done in a few minutes. As an alternative the subscise cloth may be taken out, a new one put in, and the disphragm made up again. In aft, these disphragms after a short time, dry completely and become hard; they recover their original plisability and permeability on being placed for a short time in water, or in a sait anoutton.

paces no ex anore time in water, or in a sait soutron.

During the electrolysis, sode, by is formed in the vessel 10, while chiorine loss base to the anode, are then
collected, and are evoived as guessum chiorine. Fresh
solution is added through the pipe 12, which extend
down aimset to the disphragan. During the electrolysis
down aimset to the disphragan. During the electrolysis
forms and the proper part of the solution becomes posin said, and though the processor in specific grantity; as a result of this difference in specific grantity; as a result of this difference in specific grantity; as a result of this difference in specific grantity; as a result of this difference in specific grantity; as a result of this difference in specific grantthe strolumny.

the displiragin.

The cells may be finde of various materials, such as wheeglass, or stoneware plates bedded in coment, or asphalt, as shown in Fig. 1; they can also be made of ammored concerts or of stone alsob. In small cells (up to 100 amperes) it advisable to fix the salestoc cloth cat he ball. The whole bell with the displiragin can than be placed on a corrugated wire-not, shaped to the form of the outer vessel. The bottom of this outer vessel 1.0 is advantageously made of sheet fron, and it these forms the needfactor for the current to the exchange set. In larger cells (above 100 amperes) this plan is scarcely practical; and in quick cells it is advisable to states the exchange when the cathode wits-put to the ball. In order easily to vision the displaragin, it required, withey having to stake out the ball, the lid of the latter is pade readily reinergylable.

The experimental trials with this coil gave a curcut differency of trees 50 to 60 per cent, with a conceptant of trees 50 to 60 per cent, with a conceptantian of single-ty- of 15 per such, and colorine gas 6.49 per such party, on his pulsant escapionation, the factoring states that conceptanting up to 30 per cent and 15 per cent NaOH can be obtained, and that a cell with a cathode surface of 1 square meter when worked at 60 deg. Cent. will take a current of 600 amperes with so E. M. E. of onte 4 to 444 vote.

The claims made for the new cell and process are:

The claims made for the new cell and process are:

That it combines the advantages of the earlier diaphragm processes with those of the bell gravity cell, and that it overcomes the client defects of both.

That the causes of low efficiencies in the open type of beliceliar acchecked; (a) by the presence of the diaphragm; (b) by the stretched or the fluores in the cell; and (c) by the direction of the fluor of the electrolyte through the cell. These three conditions enable one to obtain a comparatively high current efficiency

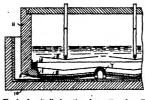

Fig. 1.-Longitudinal section of a portion of a cell.

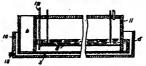

Fig. 2.—Cross-section of the alkali cell.

Fig. 8.—A battery of alkali cells in Krumman, Bohemia.

Fig. 4.—Perties of a cell room at Aschereleben,

(for the type of cell) with a fulrily concentrated solution of sodium bydrate at the eathode. The fact that the disphragm is immersed in sodium by drote solution, also contributes to its long life, and reduces the running costs of the process.

#### Notes for Inventors

Lactic Acid and Mait.—Robert Wahl of Chicago has secured patent, LOSS/GN for the addition of tactic acid to mait during a stage of the manufacture. This he does by means of a liquor containing a culture of lactic acid hacteris. It is claimed that the added lactic acid lends zear to the beer and exerts a stimulating effect upon the peptase of the mait.

A Retary Safety Razer.—George Nichols Moore of Dumoni, New Jersey, assignor to Rodary Appliances Company of New York eltj. In a patent 1,006,008 presents a safety razor which has a blade of disk form with a continuous cutting edge rotated by suitable means in juxtajosition to n guard, means being provided for varying the space between the guard and the cutting edge of the blade.

A Mergenthaler Linotype Patent,—Patent 1,067,503 to Mergenthaler Linotype Company, as assignee of Charies C. Burdine of Washington, D. C., presents in a typographical machine, transfer menne constructed to receive successively a pinrailly of separate lines or the sections and to forward them simultaneously, together with means to deliver them in assembled form successively to the transfer nears.

As Improvement in Lace Manufacture.—John E. Dudson of River Point, Rhode Island, assigner to Harry C. Chrits of Warwick, Rhode Island, has secured parent 1,047,324 for lace and process of making same in which the lace comprises wearings of three or more colors in a single longitudinal strip. The invention provides for wearing lace curtains, embrodery braids, lace edgings and insertings with any desired colored pattern of three or more interchangeathic color.

A Sectional Lifeboat.—Benjamin F. Sargeant of Fort Worth, Texas, has secured patent 1,007,276 for holding and launching machinery for lifeboats, also patent 1,007,277 for lifeboat. The patent for the life-boat above a lifeboat of two sections which fit side by side and are hinged together at the bow so that they can be opened out end to end when on shipboard and can be folded together to form a shigh boat. Each section is provided with a propeller and with an engine for driving the propeller.

An Astomatic Stabilizer.—Norman Clark and Albert E. Plank of Quincy. Himbs, in patent LOTT-900 present an acropious which has a course curred lower surface didpent to the front edge of the plane and extending back beyond the middle of the holy of the plane and exceeding the conceave surface adjacent to the pear. Thus they seek automatically to multitain stability and equilibrium in secondance with varying degrees of speed and atmospheric density and to avoid stability.

Improving the Patent Office Building.—Some recent and five or first attracted intention to the defective electric light equipment of the Patent Office and have led to the lindulation of modern wiring systems, and Ar the same time the main or rank line sweers in the besencest of the building are being extended to meet the horrowed demands and to modernize the building in this respect. New flooring has been lated in most of the examineer rooms and a general thouse-clonning is in magness. The building of the completed when the new Commulation, Mr. Eving, meaning office on August the complete of the complete of the complete special definition as Pirac Assistant Commissioner on Sepponds duties as Pirac Assistant Commissioner on Sep-

Two Patents to Charles Francis Jenkina.—Charles Francis Jenkins, the well known Washington, D. C., inventor, has had besued to little two patents, on No. 1, 097,631, for a marchine for applying caps to bottless of paper or other unsterds, and another, 1,007,432, for an improvement in dying machines, which latter includes a frear steering vane. Heretofore in a Wright machine it has been usual to pull down the rear edge of the main piane or of the nilerons or batanchy planes on the low sides of the machine when it has best its equilibrium, and to let go the other side. This has a tendescap to throw the machine around off its course, and to counteract this the rear rudder is so counced as to be simultaneously moved to neutralize this turning effect.

# All controls at your hand

ROM the small compact control box of the Aplco electric equipment you can start your motor, switch lights on or off, dim your head lights You can lock starter, lights and horn, test flow of current, light your dash

THE controller typifies the whole Apple equipment—simple, busi-ness-like, positive You get 100% ser vice from the Apico electric engine starter for this reason. It is "the starter that never stops starting "

You can depend upon it always, count on its reserve power and infallsbility Compact-it doesn t clutter up your engine installation

You will naturally prefer the Aplco equipment, scientifically developed with renested tests under the direction of Vincent G Apple himself Mr Apple is the pioneer in the whole electric starter idea; obviously his outfit is not the hurriedly-designed-to-meet-the demand kind Many engineers now agree that his idea is the right one-24 volts for starting, 6 volts for lighting, ignition aignaling, etc

hen you buy your new car demand an Apico starter Write us about it. You want to know what you can do with this starter problem, anyhow It's the most important accessory you have

You Il find our service stanons in many principal cities. Through one of-Apico starter on your present car Write us about this, too; such an un-provement will add tremendously to

on of French and Gern Strongth in Dirigible Airships

(Concluded from page ISE.)

If the actual status of this aerial fleet
is secret, that of plans and projects is ably so French inferiority is obvious and also French efforts to dimin

trike a proper balance between dirigibles and aeroplanes the great merits of dirig ibles—their radius of action and ability out at night—with their immense de —fragility difficulty of taking on stores and charging hazardous landing et etc must be con

We must not forget the terrible series of estastrophes to which nine of the great dirigibles have succumbed nor the result ant financial loss not what a correspond ing sum might do for us if applied to

viation says our French contemporary The remainder of the article deals with other countries.

midable fleet of dirigibles that is gener ally supposed, and may be considered a the third air power in Europe The mili tary school of aeronautics alone has five dirigibles. Besides, there have been or directions. 10 000 cubic meters with a speed of 60 kilometers per hour built by the National Iorsky factory the Astra XIII (French) and the 'Clement-Bayard VI which are now having their final tests (9 600 cubic meters 260 horse-power 13.5 meters diameter total length

ITAIT -Up to last year Italy had only five small dirigibles ( P1 P2, P3, P4 "15, of 4,500 cubic meters capacity F4 "15, of 4,000 cubic meters expacity and 50 kilometers per hour speed) But she has recently built two of 12 000 cubic meters capacity (Mi "M2) and the M series is to be continued with M3 M4 and M5 having the same characteristics 1. a. the remarkable speed of 70 kilometers per hour an ascensiona of action of 1 000 kilometers engines of 500 horse-power and ability to stay aloft 35 to 40 hours Italy with its five factories at Rome Milan, Campalto Verona and Bracciano is trying to create a pow erful serial fleet

building at Ferrara.)

A third series G whose construction has been decided on and of which the first will be ready this year will equa-(24 000 cubic meters) and surpass them in speed (100 kilometers per hour) if the plans of Forlanini and Major del Fabbro work out as expected The engines pro-vided to insure this sensational speed are of not less than 1000 horse-power (A ned Citta di Milano built at Baggio of 24.000 cubic meters capacity signed it is said to undertake the cross-ing of the Atlantic In short the Italian construction is sufficiently remarkable for the German officers to be following its

AUSTRIA HUNGARY -- Austrin which has AUSTRIA HUNGARY—Austria which has had no actival fleet, has recently tried to acquire a Zeppelin from Germany but Count von Zeppelin has publicly declared that he will not build vessels for any other country than Germany

ENGLAND —At present England possesses no dirigibles of great tonnage Its small dirigibles are remarkable for their in distributes are remarkance for their in genlous mechanisms notably the oriented propellers. # **Symbols** of Protection

Ancient Egyptians carved over their doorways and upon their temple walls the symbol of supernatural protection, a winged disk. It typified the light and power of the sun, brought down from on high by the wings of a bird

Mediæval Europe, in a more practical manner, sought pro-tection behind the solid masonry of castle walls.

In America we have approached the ideal of the Egyptians Franklin drew electricity from the clouds and Bell harnessed it to the telephone

Today the telephone is a means of protection more potent than the sun disk fetish and more practical than castle walls.

The Bell System has carried the telephone wires everywhere throughout the land so that all the people are bound together for the safety and freedom of each

This telephone protection, with electric speed, reaches the most isolated homes Such ease of communication makes us a homogeneous people and thus fosters and protects our national ideals and political rights

#### The Visibility of Submarines

(Concluded from page 129.)
remembered that the submarine is un

stively slow, that in war its craising depth and that at which it must attack do not exceed the draught of must attack do not exceed the granget or a intitleship, that acrophanes can readily overtake it, hover over it singly or groups, and deliver a flood of missiles on its buil, perhaps before their presence is known, the lattie, for the under-water terror, seems unequal. If warned in time, its only recourse is sudden and deep div ing, like a fish fleeing from the talons of a hawk. With its low speed and the pow-er of the aviator to scrutinize a wide area, the duration of these tacties seems limit-Aeropianes working in conjunction with tornedo-hout destroyers in attack of rines would seem to the old sailor much like that most sauguinary traged; of blue water, the assault on the helple whale by the sword fish and that wolf of the seas, the thresher, in which the mis-siles of the aeroplane would take the place of the thresher's savage blows.

se adverse conditions submarine is far too powerful and deadly a weapon to be eliminated from naval warfare. At night or in foggy weather, it is wholly safe from aeriai en under these sheltering screens, it can still feel its way to its target, while, if duty called, there will always be plenty of brave men afloat who would dare the dangers of the sunlight to steer it to attack. Finally, when we review the swift progress in the enginery of war ou the sea during the last twenty years, it seems impossible that the genins of inventor-will not find a way to conserve the submarine's fighting value, either by protecting it from its aerial foes or by enabling it to meet them on more nearly equal terms The problem is doubtless engaging the earnest attention of usvai experts.

#### John Milne

THE recent death of Prof John Milns removes from the English scientific world one of its most conspicuous figures if not altogether the creator, Mine was at least the carliest lender of the "new eismology;" i. c., carthquake-study as a branch of physics, rather than of descrip-

tive geology Milne began his career as a mining engineer, and after a good deal of wander-ing over the earth in that capacity found anchorage in the little colony of scholars and experts who were engaged in imparting occidental knowledge to the newly awakened people of Japan. He begun a twenty years' residence in Japan in 1875. twenty years' residence in Japan in 1875, when he was 25 years old. Here, as he has blauself expressed it, "they had earth-quakes for preskfast, dinner, and supper, and to sieep ou," so that his curiosity could not fail to be aroused by this obtrustive phenomenon of nature. At length, in 1880, a particularly disastrous shake inspired him with the idea of organizing the world's first society for the study of earthquakes—the Seismological Society of Japan. The pioneer work carried on by this organization placed the science of seismology on an entirely new footing, especially since it included the develop ment of the first accurate lustraments for recording and measuring earth move-As honorary secretary of the s ciety for fifteen years. Milne was its lead ciety for inteen years, billie was its seat-ing spirit. He early recognized the im-portance of erecting seismographs and seismoscopes, at as many places through-out the ceunify as possible, and before the end of his tenure of office in the Orient he had created a Japanese network of 900 statious-a far greater number than are

stations—a rar greater number than are is combined a number of successivity found in any other country.

In 1886 Frot. Milne with his Japanese white returned to England and took up his abode at Shide, in the Isle of Wight. In this quiter retreat he continued his chosen work, but new with a broader outlook, for each less which machines for starting the operation work, but new with a broader outlook, for each less which machines are to the machines for starting the operation work, but new with a broader outlook, for

he soon set himself to the task of organis ing, on behalf of the British Association for the Advancement of Science, a seisogical survey of the world. The need of an international organization had be of an international organisation and be-come apparent with the discovery that strong earthquakes make themselves felt all over the globe and cannot be ade-quately atchied merely as local phenom-ena. At the same time he wurked hard at the improvement of seismographs, with a view to providing an ideal and uniform squipment for the international stations. The great memorial of his activities since 1866 is found in the series of reports of 1895 is found in the series of repo the Seismological Committee of the British Association, of which he was and prime mover up to the time of his

#### The Death of S. F. Cody

COLONEL S. F. CODY, an American by birth, but a naturalised English sub ject, a figure long prominent in the world of aeronautics, came to a violent end on August 7th. He and a passenger named Evans were killed while flying in Cody's monoplane at Aldershot. The cause of the accident could not be ascertained; for the muchine dropped from a height of two hundred feet and was reduced to a nam of tangled wreckage

Cody was first heard from as a design er and builder of kites. So successful was he in his province that his work attracted the attention of the English military authorities. In his very original investiga-tions, he succeeded in towing boats though the water with the aid of kites and even made the attempt to cross the English Channel in that fashion. In 1905 he succeeded in elevating a man to s height of 1,133 meters by means of kites

The construction of the mechanic tion of the British military divigible "Nulli Secundus I" was of his design.

Cody was one of the ploneers in avia tion. In 1909 he constructed a biplane with which he flew 420 meters on Max 14th at Aldershot. After various mis-hnps, he succeeded in making long flights by the end of 1909. Indeed, he was one of the first of long-distance ilyers. As early us August 9th, 1900, he covered, 75 kilom eters and came down only for lack of fuel On November 4th, 1910, he covered 110 miles in two hours and twenty-four min utes. With an improved biplane of his own construction, he took part in the English circuit of 1911, but without accompiishing anything wonderful.

Cody had entered in the London Dails

Mail \$25,000 prize race around the Brit ish coast, and for this purpose had con structed a new hydro-biplane with a span

#### The Current Supplement

cord Cross-Country Flight with an American Military Monoplane

FIER having thoroughly tried out his machine at the Hempstead Aerodrome Mr. C. Murvin Wood made a record longistance flight from that field, located ear Garden City, L. L., to Guithersburg, Mid.—a distance of 225 miles—on the 8th ast, Mr. Wood intended to fly to Fort Meyer, Va., but he was unable to arrive there because he lost his way, and also because the motor failed him. He eventually landed at Fort Meyer at 5:45 P. M. of the same day, however, The start of the flight was at 4:30 A. M.,

simultaneously with the start of a special

train over the Pennsylvania lines from Jersey City. Wood rose to an elevation of about 3,000 feet while traveling to Belmont Park, and thence out over the Atlantic Ocean. Only when his motor stopped and he descended about two thou-sand feet, was he able to discern the sea beneath him through the fox. Forunately the motor re-started again, and, by ately the motor re-starred again, and, by turning to his right, he was able, only however after ten minutes had elapsed, to regain the shore at Coney Island. He must have been fully ten miles out to sea. must have been tuily ten miles out to sea. Without loading his nerve, he steered across New York Bay and crossed Staten Island, entering New Jersey near New Brunswick. Fallowing the raitroad, he passed around Trenton at 6:30 A. M., and continued southward, circling around Philadelphila he for any the results of the state of the delphia, as he feared his engine might ston The special train stopped at Philadelribia a half hour to ascertain Wood's whereabouts, and Wood passed the train during this time. From his time of passing various points the men on the train estimated his speed as from 58 to 63 miles an hour, and aithough the train made rer-ord speed to Washington, frequently traveling over 90 miles per hour, it seemed impossible to catch the fleeting seroplane. linon arrival at Washington, the occuupon arrival at washington, ine occu-pants of the train found that Wood had descended at Guithersburg. Wood's me-chanic was taken to him and repaired the engine. He found the trouble was faulty iguition. Wood reached his greatest ele-vation-7,350 feet-ut Havre de Grace. Md., but from this point his engine began missing badly until it finally stopped com pletely after he had descended gradually to about haif the above mentioned height. A southeast wind had drifted him toward Putomac River and follow this southeast to Washington. It was with difficulty that he could discern the railroad tracks, which looked like threads, and he lost these sitogether after circling around Baltimore, which city appeared as a black smudge below him. With 25 gallons of fuel in his tank at the start. Wood imd some 4 gallous remaining after his 4%hour flight. Nevertheless he obtained 5 gnilons extra from Fort Meyer, and, starting at 5:30 P. M., he covered the remaining 20 miles to that point in a quarter of an hour and voluinned from 6.000 feet in two graceful descents until he landed upon the parade ground. The machine is to the parade ground. The machine is to be given special military tests, after which Wood may return by the air route to Hempstead. It is noteworthy that this machine, known as the Kantuer-Molsant monoplane, since it was designed by Harold Kantner and constructed by the Moisant Company, worked perfectly throughout this long flight, whereas the failure of the 50 horse-power Gnome momanure or the BD horse-power Gnome mo-tor was the cause of the descent before Fort Meyer was reached. Until an abso-lately reliable aviation motor is produced cross-country flying can never be accom-plished with absolute certainty.

An Individual Shaving Cup for One
Use Outy.—A shaving cup described as
made of paraffin paper with the inner face
of the walls and bottom coated with a
table lawer of coate with a of the walls and bottom coated with a thin layer of soap sufficient for a single-shawing is shown in patent No. 1,003,644, to Edwin O. Blanchard of Randolph, Va. Is the maker solid? You need to know that, now, before you buy a car. For the day of reckoning in the automobile industry is here. Witness the sudden changes in plans, methods, models, and prices—heavy stock offerings—reorganizations—big loans—failures, more than 25 in the past year. Excessive overheads and super-expanded plants, extravagances, and mushroom methods are coming home to roost. Already several well-known

makers have failed, and cars of good reputation have disappeared from the market.

Review of Reviews says automobile stocks are not a good investment. Neither is an automobile unless its maker is sure to continue in business, making good on his guarantee, giving service to car owners, and sustaining the commercial value and public standing of his car.

#### Find Out About the Maker

Find out where the maker stands before you buy. Know that the Winton Company has always followed sound and enduring policies. No water in its stock, no bonds, notes, or mortgages to be charged for in its price, no frantic and frequent changes in models that prematurely age and depreciate prior models, no juggling with quality, no marketing of experiments, no grasping after quantity, no exaggerated price.

#### A Car of Beauty and Excellence

You can safely buy a Winton Six, for it is now in its seventh year of success—a thing impossible if it hadn't been right; made by the company that founded the industry, and the

# CAUTION

#### The Speed Factor in Collision

OW many of the millions of people who sit at the sterring wheel of their automobile real ize how greatly the smashing effects of a cullision are increased by an increase of the speed? Those who have been through a smash- and survived—have n more or less intelligent appreciation of this relation It would be interesting to learn how many out ×hip of every one hundred drivers of automobiles are usua et that the destructive effects of an overture or a callision are increased not in proportion to the but to the square of the speed A driver who his touched the curb or side wiped a funce at ten miles an hour and escaped with unexpectedly small injury is surprised at the damage which ensues in case of a collision at 20 miles an hour and perfectly dumb founded-should be survive the disaster -at the huse wrought when the speed is thirty or forty miles an hour If he were conscious of the fact that the smash lng energy embodied in his machine was four times as twenty miles an hour as at ten time thu great at thirty miles an hour and sixteen times as great at forty he might still contemplate the weekage with dismus but not with astonishment. The moral of this applied to the automobilist is that an increase in his speed is a most imperative call upon him for an increase of vigilance and caution for a nicer judgment of speed and distance and for the possession of a steady nerve and onick wit-and wee betide him in an emergency if he buye not the last mamed

So also in the larger field of ratiroading the same have exact their heavy toll with the same remorseless precision. Broadly speaking we might say that not nicue in the destructive effects of collision-should it -but with regard to every element and human that enters into the question of safe rail reading the risk and damage increase as the of the velocity. Plans if we raise the speed of an exphess brain from sixty to eighty niles an hour the momentum of the traft will be nearly doubled and practically doubled also will be the amount of crush log and rending which will take place let us say in the forward part of the train liself or in the after part to the case of a real collision of the train into which It thus before the energy of the moving train has been expended and it comes to a state of rest. Furthermore the higher speed imposes a much higher stress both upon the trilin liself and upon the track and track structures over which it rups. The distances between signals must be greatly increased stace with brukes of the same officiency it would take a much longer time sicw d wn the faster trab

Will Westinghouse spaking upon this subject has recently stated that when emergency basks are set on a train which is toming at it into 6.9 miles an hour the train will be still mining at 10 miles an hour the train will be still mining at 10 miles an hour when II has advanced 1 100 feet from the point of application of the bracks whereas a train would be stopped altogether to 4.100 feet if its speed were culy 60 miles any hour

#### Bigger Lifeboats for Ocean Liners

This loss of the Titunic led to the formation of several important committees which we sin structed to havestigate the disaster and make suggestions designed to promote the castinction or safer whips better methods of Bit bout countra thou and spwage, and a general all around improvement in the conditions aftering safer, as see [or these committees one of the most september was that appointed in terral little and the property of the property

made public, is a most valuable sudiction to the Miles. ture on the subject, abounding as it does as suppostions which are at once conservative and prestical.

ture on the subject, accounting as 1 speed as suggestion.

B) for the most solvable suggestion—one that is no ensemble, we had almost said obviens, that the weights is that it was not made long ago—is that the size of infeboats shall be very greatly increased. The committee proposes a type that shall be of neswerthy size, so the size of the committee proposes a type that shall be of neswerthy size, and shall provide accommodation for no less than 250 passengers. They will be decked over throughout the greater part of that length and they will be driven by gasoline engines of sufficient power to give them a fair speed

The question insturally arises as to how boats weight in pointy 30 tions appear are to be launched and the committee suggests two alternative methods. They be live that daylts can be designed capable of being worked either by hand or by power which would easily made to the second of the size but they consider that in some cases a botter plan would be to permit the life boat to find off or the ship new down of the two methods we think that this is in question that the fourier is preferable. It should not be a difficult matter to design davits and gear compact and equally controlled which would how the a difficult matter to design davits and gear compact and equally controlled which would howe a 28-ton beat too the water with the same dispatch and certainty with which the present-5-ton boats are almanched. On the other hand there would be many risks insequantly from the halp as side foundered. Should the vessel go down on a fairly believe to the side of the control of the shap as side foundered. Should the vessel go down on a fairly eneme to damage but in the even of a ship soing down in the head at such a tyrene angles as were assumed to the control illustration of the side of the side of the two the head at such a tyrene angles as were assumed to the treatment of damage but in the even of a ship acting down in the head at such a tyrene angles as were assumed by the Tital illebusts as heavy as those suggested might break away from their cradies and be stove in hefore they reached ith water.

before they recched the wates. It is easy to be wise after the event and now that this committee has made this sensible suggestion to increase the size of lifebours it seems old that it should never have occurred to our must acciditate to increase the size of the libebout in some proportion to the avel increasing size of the ships that carried thus The fact that the life boost of toda is pastile ally of the same type as that in use fifty years ago shows how that false sense of security which led to lik lows of the Titank has caused the naval article tech and the shipowars to pas seem talention to the lift boat it itself. Become increasing, its size and betteing its construction little has been done toward its happroximat—it remains to day the same clumwing propelled craft that has littered the upper decise.

of our passenger ships from time immu morial.

The best lifebont is the ship itself, and it is encouruging to note that this is the conviction which seems to prevnil in all the technical discussion which followed the disaster of last vent 1 safe ship needs no life boat and the long line of these craft lining for hun dreds of fest the upper deck of our great passenger steamers is in itself a confession of failure a tacit admission 14 the shipowner and by the Govern that makes the laws regulating shipping matters that although we have succeeded in making our ships large and fast and comfortable we have not succeeded in unking them absolutely sufe. The very latest and making them insountely some The velv late bargest transatlantic liners such as the Maun-the Imperator and the remodeled Olympic been built with a special view to security Maurotante have foundaring Theoretically thoroughly subdivided and navigated ships need no multiplicity of life hoats if they are to be carried it is obvious that the 28-ton boat us proposed by the Boats and Pavits (om mittee represents the proper type. The largest of the ocean liners carries over sighty books of the prescut type collapsible and otherwise. They are an abominable nuisance to everyone concerned and take up much room that could be used to great advantage for the benefit of the passengers. By adopting the 250-passenger capacity beat suggested, eighteen to twenty lifeboats fifty feet in length would take the place of the eighty or more in a ship of the inrgest size The gain in safety and comfort by the use of such large boats would be immense They uld be thoroughly senworthy, and being power-pro pelled they would be able to make port, or at least steer for the location of the nearest ship as indicated by Bircless telegraphy

The recommendation of the committee that if smaller beats of the size now in use are placed on beard the should be used in parallel tiers with provision for launching on either side of the vessel is particularly interesting to the Schpthyle America, since this was the plan which we suggested and fillustrated at the time of the loss of the Triani.

Ancient and Modern Research on the Blood

The intimate connection of the blood with life
the notice of man From the very first he was

I to associate the crimson winn with bettle

and fleath, but the feus standards with processes has become latery to a large event of the control of the cont

But the circulation of the blood is after all a men mechanical phenomenon comparatively obvious in charso much so in fact that we are somewhat supprised that it should have so long escaped notice Much less obvious though of the highest importance, are the less obvious though or the interest importance, are severe-chemical processes in which the blood is involved and vet the understanding of these began at a time when the science of chemistry itself was still rather radimentary. Thus for instance it was pointed out as early as 1669 by Richard Loyer, that arterial blood owes its rich red color to the action of the air or as we owes its rich red color to the action of the air et as we mow should are to existent as the same year John Mayow showed experimentally that in respiration just as in combustion a constituent of the air is absorbed. That the heat of the body in due to this process was rightly discerned in 1871 by Thomas Willia, Similar observations were made in 1860 by Robert Boyle while the discovery that respiration produces carbon dioxide as a waste product, is due to Joseph Black (1757) With the field thus prepared for him Lavaisier had no difficults in fully appreciating the significance of then newly discovered oxygen for respiration and in 1777 he pointed out that oxygen is the only constitu out of the air which plays a direct tole in tespiration The investigali m of the chemical nature of the blood itself was necessarily reserved for a somewhat date involving as it does organic chemistry. In it cannot be said that all questions relating to the chemistry of the blood are at the present day complete-Much work of the biginest field has been done in our own country by Prof E T Reichert who has hild down in a memoir published by the Carnegle Institution the results of his researches on the crystallography of hemoglobins. The differentia has received considerable attention on account of the legal importance attached to such tests in the prosecution of criminal cases but the methods of examination ed by 1 rof Relebert for exceed in their billies such comparatively crude methods of different thation for by their means it is possible to establish the relationships of different species of animals. An article to this week's SUPLEMENT gives a detailed Him-

strike in this week's CIPLEMENT gives a detailed limitated account of this development.
While the blood has a definite and important familion to fulfill in health this does not exhaust the pregramme of its vital activities For it is inrucly owing - Initiated in the blood that we use special proce able to waid off or overcome attacks of various dis-eases. This is actileved partly through the formation of so called anti hodies in the blood and partly through a literal devouring of the disease germs by the amor bold white corpuscles of the blood. I nfortunately the victory does not always lie with the defending forces of the body and the so called blood parasites represent I nfortunately the a formidable army of enemies, among whom some of at deadly are the germ of the sleeping sickness and that of malarial fever both introduced into the body by the bite of insects Much work has been done in recent venrs and be it gratefully acknowledge ul work in the study and subjugation of these invisible form

A review of recent progress in this field by H G Plimmer will appear in next weeks issue of the Scientific American Supplement

The Coal Beaucrose of the World use the subject of a 1,900-page monograph in source of publication by the executive committee of the Twelfth International Congress of Geology, under the editership of Mosses, Wm. McInness and D. B. Dewling. An atlas of about 70 conceed maps, 14200 inches in else, will accompany the work, and about 120 maps will be southered through the test volume. This publication will represent the results of the most through investigation ever made of the distribution of any mineral coropi iron, which was the subject of an investigation carried out under similar auspices there years ago. piece three years ago.

American School of Archeology in Chin American Subsel of Archeology in China.—A committee has been apoptized by the Council of the Archeological Institute of America to investigate and report on the plan of establishing an American school of archeology in China; its objects being: (1) To prosecute archeological research in castern Asia; (2) to afford opportunity and facilities for investigation in Asiatic archeology; and (3) to preserve objects of archeological and cultural interest in museums in the ountries to which they pertain, in co-operation with activing organizations for a kindered purpose, such as the China Monuments Society, organized by Mr. Frederick McCormick in 1908 at Paking.

The Beforeign Telegosper.—In the Scientific America

Protential McCorminic in 1908 at Paking.
The Reflection Telescopes—In the Scientific American of July 12th, 1913, there was published an article on the reflecting telescope, by Edward A. Path, director of the Smith Observatory at Beleit, Wis. Such a large of the Smith Observatory at Beleit, Wis. Such a large mumber of longuities have been received, both by Mr. Path and ourselves, asking for further information regarding this type of telescapes, that we desire to call attention to Nos. 1818 to 1917, insientive, of the Scientific Austrace, Strummanner in which was much labeled. attention to Nos. 1818 to 1917, insiderive, of the Science Trife Aussican Supressions, in which was published a series of six articles by G. W. Ritesbay on "The Modern Reflocting Telescope and the Making and Testing of Optical Mirrors." These articles treat the subject in detail and give much valuable information. Blood and the Conservation of Basegy.—While the study of the blood is sensestisfly a matter of biological

interest, it is a somewhat remarkable fact that it also furnished the due to Julius Robert Mayer for his discovery of that fundamental law of physics, the law of conservation of energy. Mayer observed, while traveling as a ship's surgeon in the tropies, that the venous blood of his patients (in the days when blood-letting plood of the patients (in the case when noted-acting was still in general vogue) was very appreciably brighter in color than in ordinary practice in the temperate zones. From this he rightly concluded that there was a definite relation between the chemical action going on in the blood and the amount of work or heat fur-nished by the body, and thus following up his argument point by point, he was finally led to the co that the total amount of energy of a given system is constant, that energy can neither be created nor destroy-ed, but only converted from one form into another.

od, but only converted from one form into another.

A Usique Climatic Observatory is maintained at Davas, Switzerland, by Dr. C. Dorro, who has recently published the results of the first three years' work at this institution. Dorno's observatory is remarkable for the fast that it is securing records of many important but labberto neglected factors in climate; it contexts, for example, is a striking manner with the conventional methodologies station maintained by the Davos Kurversin. Special attention is devoted to the measurement of radiation, insteading separate records of the thermal, laminars, phetographic and photo-electric intensity of direct radiation from the eur; also the combined radiation from the eur; also the combined, and the like. Already some interesting discoveries have been made as to the composition of the famous places sumshine, and its fluctuations with hour and sasson; facts that have important therapeutic againstances. The name, and its nucerisatons with nour and season; inside that have important therapeutic applications. The meet intense ultra-violet radiation eccurs in summer, and this, it is suggested, explains why the invalids at Davos suffer with "gladet-burn" at that season. A sin-Davos suffer with "glader-burn" at that season. A single summer day may give as most better-richt resistion as a whole sensith is wrinter. On the other hand, the theorem's resistance of strong-pheric electricity are also underded on its acquestions of strong-pheric electricity are also underded on its acquestions with multifactors methods developed making during the past decade. Beamslorf electronsiers are used as accuse conditators registration, in its remarkable engineering sed methods the institution, may be said to be a generation in advance of the engineer method engineering accuracions of the world—in which respect is may be alseed with the observatory of the Etros, in Spain, a, action of which was published in the Equation Assessment of October 10th, 1910.

states type of acroplane will be used. The models is shaped like a letter V and has no tab.

Legacia the Legacia Company. -In the measure report of the campany which constructs the factorial report of the campany of the campany which constructs the campany of the cam practically half of the working capital. Inasmuch as large sums have been received from the German government for experimental purposes, and also consider-ing the fact that the price of the vessels has been doubled during the past two years, having mereased from \$125,one to \$250,000, this loss seems excessive. This can be accounted for, however, by the high cost of experi-ment and on account of the fact that no absolute standard model has been adhered to, although all the Zeppolius have been outwardly similar in appearance,

A New Height Record.—The breaking of world's records in almost any sport has become so common that it often fails to attract the deserved amount of attention. The latest height record for an aeroplane, for this reason, has gone almost unheralded, and few besides those actually interested in flying realize or appreciate the accomplishment of Harry G. Hawker, who, on June 10th at Brooklands, set a new British statude record for pilot and passenger by rising 13.400 feet, a distance equal to more than two and a half miles. He used an 80 horse-power Sopwith tractor biplane fitted with balanced ailerons. On the same day he also broke the British record for an altitude flight by rising with two passengers to a height of 10,800 feet.

Piest Air Collision Case Settled. After a litigation of bearly three years the action between M Thomas and Capt. Dickson, as a result of a collision between their acroplanes while flying at the Milau meet in 1910, has at last been settled. It was recently decided that has at last been settled. It was recently deeded that Dickson was responsible for the accident, and he accordingly directed to pay \$1,000 damages to Thomas and \$2,000 to the manufacturers of the Automette acroplane which Thomas was flying at the time of the accident, heades being ordered to pay four fifths of the cost of the suit. In the original bill of complaint Thomas had asked for \$16,000 damages, while Dickson had put in a counter claim for \$20,000 for injuries and for the destruction of his Farman aeroplane

The New French Military Aero Stations. first of the military acroplane stations built with the funds raised by national subscription in France has just been completed at Everenx, and it contains a model hangar with annexes such as repair shop and the like, also a telephone post. This statum is the first one of fitty-litree aeropiane statums which are to be completed by next October, and in three months it is stated that there will not be a single point in the triangle extending from Paris to the frontier where an aviator will be more than 25 miles from a well-organized landing station. Besides this. the principal acrial routes between the large cities, such as Paris to Marselles and to the Channel, will have similar posts placed along them at short

Wreck of the Schütte-Lanz Dirigible.-The stren and lifting power of balloons is seldom realized by the reading public until an air craft suddenly demonstrates its possibilities by cutting up capers without the guiding the possibilities by criting up capaca within a single hand of a pilot. This was forcefully brought out on the recent (also its last) flight of the German dirighle "Schütte-Lanz I," which sailed from Königsberg on July 13th for Berlin, but was compelled to alight at Schneidermühl to replenish its supply of hydrogen. The ship was moored to an anchor sunk six feet in tho ground and as an additional presention a force of 300 men from the neighboring garrison were ordered to be ready to hold the balloon down in case of a storin During a high wind one of the cars, a motor and several instruments were damaged. While repairs were in instruments were damaged. Within repairs were in progress a violent gust struck the vessel, raising the stern about 100 feet in the air. The soldiers were so completely taken by surprise that all but two released their hold on the ropes. One of these fell from a height of 30 feet and was badly mured, while the other clung to the vessel until it had risen to nearly 1,000 feet when he also released his hold, and dashing earthward, was immediately killed. The ship hovered over the town for nearly an hour and then gradually descended. Driven along by the wind close to the ground it bowled over atong by the wind close to the ground it to owner ever trees and telegraph poles in pussing. A large body of peasants endeavored to arrest its flight by tying its cables to fir trees. The straining of the large bag, however, soon tore the trees up by their roots. When a sufficient quantity of the gas had escaped the ship collapsed in a forest with its framework broken and

A Curious French Gidding Bost  $O^N$  the Schre at Triel, France, a curious looking  $O_{\rm craft}$  is attracting much attention. It is a water glider propelled by means of an aeroplane motor and screw propeller, but resembles in no small de-

gree a seew or raft. This new "fiyer," as it is termed by its designers, is owned by M Paul Tissandier, and was built for him by Courte de Lambert.

The glider is really a kind of hydroplane, for il consists of five light floats or steps. to which the deck is attached, the total length of the craft being 7 meters, or nearly 23 feet. It is equipped with a 160 horse-nower Gnome engine, and is credited with a speed of 85 kilometers (nearly of with a speed of so knowleters (heart) 53 miles) per honr. When skimming along the surface of the water at this speed, the floats are almost entirely out of the water, and if wings were attached at the sides the craft could be converted luto a hydro-neropiane

gilding hoats and similar machines date province none and aminer machines date back nearly twenty-four years. In 1893 to a Tissandter glider with the propeller under water, and a speed of 28 kills per hour was obtained. Several different motors were tried by Tissandler and it was with his Buchet engine attached to a dirigible balloon that M. Santos-Dumont made his first memorable trip around the

#### Shifting Gears by Electricity

WiTH the successful employment of electricity both for lighting the modern automobile and for starting its motor as well, an additional step toward the evolution of the hoped for "push-but-tou-operated" car has been made. And now the gear shifting problem, too, has been successfully solved with the aid of electricity

Nearly a year ago the first electrical device designed to permit quick altera-tion of gear ratios by the mere depres-sion of a button made its appearance in Detroit, Mich., but it never proved a com-mercial success. Recently, however, a second device of the kind was placed on market, and so successful h en that already it has been adopted as

standard equipment by several prominent automobile manufacturers, thus making plain that it is a device that must be reckoned with. Like its predecessor, its vital principle is magnetism. It operates in conjunc tion with a combined electric lighting and engine starting system.

Despite the complication that generally attaches to tilings electrical, the mechanism is extremely sim in its essential elements; the whole of it is contain mely simple within the gear case, and it is therefore fully protected from accidental damage and from dust and dirt. In fact, it is more mechanical than electrical. Instead of

being alternately connected with a slid ing hand lever working in the ordinary li-gate quadrant, each of the gear shifting arms has its own powerful solenoid which is operated from the batters that server to operate the engine starter. The am of carrent drawn is small - about 15 am peres-and us the contact is only momen tury the effect on the battery is negligible, particularly in view of the fact that the initery is constantly charged. The pull of the solenoids has been calculated as about 150 bounds, which is several times ordinarily obtainable with the usual hand lever, consequently genrs are quick ly and eastly shifted

The control of the apparatus is vested in a row of six small buttons arranged as shown by the accompanying illustration, on one of the supporting arms of the steering wheel. it will be noticed that the genr shifting lever is absent, the rematiding lever being the emergency brake control. The control buttons are arranged tike the luttons of an inter-communicating telephone system; which is to say, that when one is depressed it stays down that when one is depressed it stays down null another is depressed, when the first automatically springs up. This is to pre-vent the possibility of two gears being en-gaged at the same time, though even if this were possible the pull of opposite aboutly would esselv in an another in the pull of solenoids would result in no movement.

All of these six buttons, merated from 1 to 4, for All of these six buttons, numerated from 1 to 4, ror the four forward speed, "N" for neutral and "R" for reverse, are connected in multiple with a master con-tact operated by the clutch pedal; hence, say of them can be left depressed indefinitely without causing a

The deck of the glider is built over five wide floats

An extreme case is found a much filled out with air it is pred a shield in front, preventing it fre ing on the heart and esophagus. . Were it not so, the bladder would blad blood circulation and respiration. The the filling out of this organ. In some cases the bindder has a fine clastic ture membrane surrounded by a stoner, on thus resembling a rubber tire.
While river bottom fish have an or

swimming bladder, in sea bottom fish it awimming blauder, in seas cotton and disappears altogether in most cases. Size nature of the bottom may account for this difference. The air bladder of a fish entering and leaving soft mud has time to itself to the different pressures. In the case of the Pices, living in sea bot-

tom to a hard and compact sand, the fish makes a great effort to penetrate into the sand, and when it comes out suddenly its highly-compressed bladder would expand so much that it would be in danger of bursting. Hence, in this case the bladder disappears, owing to adaptation to surroundings.

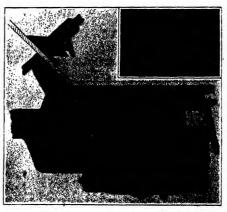

#### Caste in the Social Insect

THE study of social insects such as the termite has niways is no of interest, especially regarding the division of such insects into castes, each caste showing

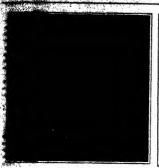

a difference in appearance. The white ants have several castes such as soldiers, workers and reproducers or sexuated in-sects. Owing to their defensive rôle, the soldiers are wingless, but have very strong mandibles, while the works with building the ant-hill and bringing in food, have a characteristic form; like soldiers, they do not reproduce. On the contrary, those of the caste known as re-On the producers have their organs well devel-oped, and their only office appears to be that of reproducing the species.

Prof. Bugnion, a Paris scientist, is oc-cupied with the problem of ascertaining when these different forms of the ant be-gin to appear. Hitherto it was thought that after hatching, all the small ants had that arter datening, hi the small arts and the same shape, and later us became sol-diers, workers or reproducers, this being accounted for by differences in feeding or the presence of parasites in the body. author however shows that on leaving the egg the insect has its characters well marked so that the casts can be seen. For instance, in the Estermes Isonatria the soldiers have a frontal horn which is tacking in the others, and this horn is observed even in newly-hatched specimens. In other species the mandibles can be dis-tinguished even at this saviy stage, and in several the division the cases, 'the there of sexes, before the birth of the larve.

### Teaching from the Child's Point of View

A New Science Created by Prof. Ernst Meumann

By Dr. P. R. Radosavljevich, New York University

Apparatus for measuring blood pressure

ns of education underlie all vital prob-You will find it in the fact revolution in the history of thought was out reason that we call our science of educa "Todagogy;" for to the Greek paidagogos was a the method of bringing the undeveloped mind to the mind of a child this luftuen shield to be attained. In a broader sense, educa-discipled every influence that a mentally strong time exert on another person. That includes medication. But in a narrower sense, educaschool education

hool education begins and ends with the alt; for the adult teacher works backward on a imposes sis own ideas upon the school child. For that rebush this ectence of podagogy in this twentieth century has developed no further than physics or natronomy had developed in the time of Galileo, and that, despite has averaged in the time of Galileo, and that, despute the fact that pedagogy is two thousand years old. What a peradox it is that scientists opend years of the control of same plants, but have as yet lavished no attention, scientifically speaking, on their own children and pupils.

Perents devote more time to the cultivation of gardens to embroidery than to the education of their off-Even governments have as yet done pracnothing in endeavoring to ascertain scien what are the conditions that are most favorable to the child's physical, mental and moral develop-ment, as compared with what governments have done in the development of agriculture along scien-

Aftar centuries of waiting, we at last find a begin-ing made to establish a new science of experimental bedagagy, a science which instead of following the aid a priori methods, accepts the surer method of exentation and acquires more accurate and positive knowledge about pupils—a knowledge both qualitative and quantitative, by means of which we can free oursaid quantitative, by means of water we can ree our-selves from the tyranny of traditions as to what constitutes an average school child. When that science is developed we shall be etter able to understand what basis there is for the pedagogical belief that schools must be respectors of Individuality.

The new science of experimental pedagogy suches all its problems from the standpoint of the sool child. As might be supposed the new movement originated in Germany, the land of pedagogy. And the man who has made it possible, the man who gave the first impetus to the movement, is Prof. Ernst Meumann, now in Hamburg.

Meumann the Creator of a New Science.

Experiment is the guiding idea of Meumann in treating educational problems. His pedagogical laboratories is erg, Münster, Halle and Leipzig became the conclum senctorum of all his numerous pupils who would know the aducational truth and understand the workings of the child's golnd and the workings of the child's mind and the scientific character of pedagogical prob-lems. But our chief obligation to him comes from his numerous experimental probangetics writings. His "Lockures for the Introduction to Experimental Peda-sogs" (in 2 wals, indicate a vigorous properties of the kind as per in print. From the locking of the kind as per in print.

Pedagogy in this alleged twentieth century is bout in the same condition as was astronomy in the time of Galileo. A science is needed to deterr individual differences among children. When that science is developed we shall be able to classify, science is developed we shall be able to cussing, grade and promote pupils scientifically, and not divide them according to ages or slees or school marks as so note foolishly do. Some day we will have a real science of experimental pedagogy. A heriunius has been made by Prof Brust Was This article, written by one who has st him, sets forth in a simple way the basic principles of that science. Some day when the new pedagogy will have assumed the importance and dignity of total name assumed the importance and alputly of botony or ohemistry so well find in overy large community a clinic where parents and teachers may receive advice on school matters, a bureau which well not as a consulting empineer in educa-Honel affairs -- Porrow

what extent the method of experimentation has equipped educators with knowledge as to the facts of school children's development and reaction under in-

an does not agree with James, Minsterberg and other well-known psychologists who claim that education has gained little from experimental psychological investigation; he holds that it has gained very much and pleads that pedagogical experimentation is slowly emerging as a field quite distinct from purely perimental psychology because its problems are more implex and are made with practical ends in view Experimental pedagogy does not try always to reduce all problems to their most elemental form; it is more synthetic, while experimental psychology is more syntacte, while experimental psychology is more analytic. And then the teacher's aim is not the ac-quirement of psychology as a critical doctrine, but as an experimental study of his own school questions. Experimental pedagogy deals, therefore, mainly with the school children, including young women and you men. Meumann aims (1) to show that experiment en and young pedagogy enables the individual teacher to be at all ite clear in his own mind as to the justification of his pedagogical measures, and (2) to impress upon the teachers the necessity of seeking to answer upon the teachers the necessity of seeking to answer all pedagogical questions from the pupil's standpoint in order to rid themselves of the conception current in older pedagogy that the child is merely an adult on a small scale.

Statistics vs. a Knowledge of the Child Mind. Although Messmann admits that pedagogical theory has been the chosen Seld of amateurs and of self-edu-cated persons, he fully recognises the folly of those

modern experimentalists who pile up statistical masses of apparent facts without, as a preliminary, striving to get a thorough-going analysis, I e., without a full and clear conception of the psychological units in-volved. We have to keep in mind that a statistical conclusion is not a psychological interpretation, and that a psychological possibility does not mean necessarlly a pedagogical necessity.

ann shows that in educational theory as well as in educational practice new fields and standpoints have been acquired or at least confirmed scientifically which previously had only a remote connection with school education or none at all. Educational legislapedagogical therapeutics or orthogene must be based on science, i. e., on general scientific truths, not on educational idiosyncrasies and personal partiality. First of all we must see the truth, i. e., we must know exactly what pupils are, what their development is, and for what they are fitted.

What is Intelligence?
Take for example the problem of intelligence. the differences between the bright and dull pupils in kind or in degree? What is really intelligence? Is it inherited or acquired, or both? Can we distinguish general intelligence (innate, unspecialized mental efficiency) from acquired knowledge, interests, dexterities, and from specific endowment, aptitude or talent? Some believe that the child is bud by nature talent? Some believe that the child is bad by nature (Francke, Palmer, Graser); others claim that the child is good by nature, but it is spolled by its environment (Rousseau, Pestaloggi, Froebel), still others claim that a child is neither good nor bad, it has only general unspecialized dispositions which may be deveigeneral unspecialized inspositions which may be devel-oped in either direction (Wundt, Judd). Or, in regard to the pure intellect some believe that the child's in-tuiligence is inherited (so-called notivistic theory of Galton, Pearson, De Candolle); others claim it is acquired (Stills's empiricism); and those who share the theory of genetism (G. Stanley Hall, Dean Balliet, Horne) say that the child's intelligence is both inherited and acquired.

Meumann thinks that all these more or less different theories may be good for their own purpose, and a teacher who is dealing with a normal school child must judge a pupil's intelligence not only by its ac judge a popil's intelligence not only by its accom-plishment of school tasks, but also by the energy (effort and time) expended in reaching this goal. Thus, three pupils may have the highest mark (A) in solving an arithmetical problem, but one did it in 3 minutes, anarithmetical problems, out one did u in is minutes, an-other in 80 minutes, and the third in 80 minutes All three had the same, highest mark. Which is the bright-est? Or in memorizing a poem all three receive mark A, but one needs 3 repetitions, another 30 and another 60 repetitions. Who is the brightest? Meumann gives

therefore, the following formula to de termine a child's school intelligence

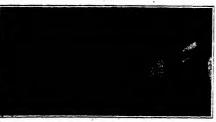

School Intelligence ==

Energy Expended Estimating Intelligence.

He mapped out a plan of studying gen eral intelligence of normal pupils, dealests material which involves the ability

ing with it not as a whole, but only with some of its higher capacities. For these higher functions of intelligence he sugto work with abstract material in a purposive way, seeing new relations and breaking up old combinations. He disagrees, therefore, with those (e. g. Eb tus) who claim that intelligence is the capacity to form new and original combinations, because a witty man does

### The Vast Ore Deposits of Cuba

By Heary Hale us see pages 146 and 147 )

The discovery that Eastern Cuba is over-laid with a deposit of Iron, accessible for mining without tunnelling or shafting, which aggregates fully 500,000,000 tons or more, means that a new source of supply is available for the American iron and steel industry that is of the greatest importance. Less than ten years ago was this deposit investigated. In 1904 samples of ore were taken from a small area that were found to con-tain over 50 per cent of iron. This was followed by 8 more exhaustive study of what is known as the Mayari district, by pits 300 feet apart, with borings made with a 2-luch carpenter's anger in the bottom of each pit. At first, each foot of pit the borings were analyzed separately; but the ore proved of such uniform quality that samples were then taken of each 6 feet, by borings only, and the distance between these was increased

lings only, and the displace between lines was increased to 1,000,1,000, and 1,750 feet.

The only from ranges in this country that can be contrasted with the Culous deposits in extent are the Superior, which in their earlier bistory supplied 75 per coul of the ore consumed by American furnaces. James J. Hill was the ploneer in opening the Superior The large quantity excavated from the Menomince, Marquette, Mesabl and Gogebic—the largest ore beds—can be realized when it is shown by authoritalive records of production, that during twenty years mining has been conducted on such a large scale that

thilly 250,000,000 times have been taken out.

At the present time the annual output of ore is nearly 60,000,000 tons from the total ore mines of the country, of which Superior ore now represents about SOUND, ON tons of available ore of a quality for smell-ing, in contrast to the 75 per cent of the entire Ameri-can output in its earlier era of mining.

The ore in its natural state contains a very large per centage of water, which increases to some extent with the death below the surface. Near the surface it is red r, with somewhat granular structure. The color gradually changes with depth, finally reaching a bright The consistency also changes toward the bot tom to a ciay-like, sticky mass. The relative proportion of red and yellow ore is quite variable; in some places the yellow reaches close to the surface, while in others the red extends almost to the underlying ser-

In the Mayarl division of the Spanish-American Iron Company, the ore lies on an irregular platean, about 15 miles long and 5 miles wide at the widest point, entirely covered with pine trees and brush, which gre directly on the ore. The elevation at the northern extremity, which is approached by the railroad, is about 1,700 feet above see-level. At the southern end the general elevation is about 2,000 feet. Ore is removed by means of scraper-bucket excavators and steam-shovels, these muchines toading into special standardgage, side-dump steel cars of 100,000 pounds capacity.

The Spanish-American from Company is also operating hard-ore mines of the Daiquirl group, on the coast of Cubs, about difteen miles east of Santiago. coast of tuna, moon inteen miss east of Sautingo.
The main ore properly al Dalquiri, once considered as
three separate unlines, San Antonio, Lola, and Magdi-lenu, has now developed into a practically continuous
body of orc. The ore in the Lola mine can easily be body or ore. The ore in the Lois mine can easily be distinguished from the waste by its darker color. The waste-banks are on the right and the ore-lowering in-clines on the left. Both the ore and the over-burden moved from a series of benches. Fourteen steam shovels are employed for stripping, the largest of which is a 90-ton Marion carrying a 4-yard dipper All are served by iccomotives and trains of side-dump cars for removing the rock to waste-banks on the back side of

On account of the rock being mixed more or less with the ore, it is necessary to load all of the ore by hand iulo smali curs, which are run to lowering-inclines These inclines carry the ore in skip-cars to the main-line railroad, which runs from the foot of Lola hill to in Playa, the shipping-port at the coast, four miles from the mines

A hoisting-incline is provided for raising coal, ms ery, aml general supplies from the main-line railroad to any level of the mine. A modern nir-compres-sor plant is located along the rallroad near the San Antonio mine, and a pine-system is arranged to furnish compressed air for tunnel-exploration and for g crai service to any part of the mine—Steam-drills are used in the principal blasting-work—Ore is also brought from the Berraco and Signa groups of mines, located trum the betrace and signs groups of mines, occured to the east of Dalquirl, over a marrow-gage raifroad laining the standard-gage main-line about two miles je-low Dalquirl mines. All of the ore is crushed before shipment in a Gates crusher-plant to slow-suitable for use in the blast furnaces.

use in the hist trunces. The contour of the ground at the point where ex-cuvations were begun, in the Mayari district, though ampearing to be quite regular, is not ideas for steam-shove operation. The depth of ore is not uniform,

in many places the underlying rock projecting far up into the ore, even to the surface. The general slope of the ground, even in the most nearly level places, is quite irregular. Therefore, it is difficult to find many places where it is possible to operate a steam-shovel for an extended period in a cut of economical depth without including a considerable portion of the rock with the ore excavated. For this reason the acraperluicket excavators are more satisfactory as well as more economical for excavation, although their ospacity is considerably less than that of the large-size shovel used. Three of these excavators are now at work, together with one 90-ton Bucyrus steam-shovel. The vators operate 1.25-cubic yards Page buckets, ough a larger capacity of bucket is contemplated. The bucket swings through a radius of 80 feet, and without difficulty removes all the ore for a width of about 100 feet down to the rock bottom, the projecting rock and stumps being discarded. Each a crew consists of one operator, one fireman, and three pitmen. As the machine works up hill or down hill continually, and the track follows the same grade, cars can be dropped down by gravity to be loaded as needed, with a minimum amount of locomotive service.

The nodulizing plant, located on the east side of the The hodulizing plant, located on the sear side of the raw-ore yard, consists of twelve rotary kins, 10 feet in diameter, and 125 feet long, set at an inclination of % inch per foot, and 20 feet apart. The kins are of the type commonly used in the manufacture of cemest. The diameter, however, is unusually large in order to overcome trouble from "ringing-up" in the hot sone, which often causes serious delays in the operation of klins of smaller diameter. Each kiln is carried by two steel tires rigidly fastened to the shell. The cut-steel stee: tree rigidly materies to the shell close to the tree near the cold end is 132.78 inches in diameter, and 4 inches in pitch. Each klin is driven by a 35 horse-power variable-speed motor. A 7.5-ton over-head electric traveling-crane, carrying a man-troller with 3 cubic yards grab-bucket, is provided for removing the nodules from the trough of the nodulizing plant and loading them into 50-tou electric transfer-cars on the track passing alongside of the trough.

The construction at the water-front is somewhat unusual. Close to the front leg of the bridge, and parallel to the rount of the front reg of the brings, and paramet to its runway, is a treath extending over one side of a trough. A transfer-car brings the nodules from the nodulising-plant, and discharges from one side into this trough, in position to be readily loaded into the vessel, or to be moved back to storage under the main span of or to be moved back to storage under the main span of the bridge by the grab-buckets. The bottom of the trough is one foot above high life. Its outer wall is formed by planking spiked to a row of piles. All of this construction, being above the water-line, is not subject to damage by the teredo navalis. From the outside of the trough-wall the bottom drops off at an a 45 degrees to 28 feet deep at the fender-line, which is approximately under the hinge of the boom of the

vide a suitable harbor. A basin 1,500 feet long, 200 feet wide at each end, and 400 feet wide at the widest point, was dredged to a depth of 28 feet. The approach-chanwas dregged to a depth of 25 see. The approximation, etc. 2,500 feel boulg and 200 feet width, was dredged to the same depth. Felton, on Cagimaya Bay, a well-protected branch on the south side of Nipe Bay, close to its entrance, has proved a very safe and satisfactory

Each year more investigations are made of the de posits beyond the mines opened, and the results confirm the statement that this and the Mayari beds con-tain fully 500,000,000 tons with an extensive area still d. The tonnage available for steel making may be 600,000,000 or more, as only a half militon toms or more of ore are mined annually.

#### Treating Tuberculosis by Marine Micro-organisms

M UCH has been written of late on Dr. Friedmann's M tuberculosis cure by means of son turtle microbes. in a memoir submitted to the French Academy of Science, Dr. Raphael Dubois, professor at the University of Lyons, draws attention to his own experi ments on similar lines, begun as far back as in 18
Twelve guines-pigs inoculated with tuberculosis crobes, so as to become manifestly infected with the disease, were treated with a micrococous derived from a pearl-producing shell-fish of the Hyères seacoust, and with a single exception, were kept alive ton months afterward. The seeming curative effect of the effec-corcus was put down to its "calcifying" action as allows

conces was put down to its "cuttilizing success as a little foresistion of pental.

Now Dr. Dubols recently obtained from the recent department of the Toulon shughter-house some conscionations, as foresist special special cours concertions, as foresist special part of the conscionation of the observations of the conscionation of the conscionat in the image of two oxen seemingly in course or issuing, and in the liver of a tip, respectively. From the distinct current shells of these lesions he prepared estimate of several species of becterin, one of which, we had had been several species of becterin, one of which, we had had been several species of becterin, one of which, we had had been several species of the several species.

#### The Current Supplement

I N this week's issue of our Supplements, W. J. Hum-phries contributes an interesting article in which he shows that the presence of volcanic dust in our atmo-sphere has probably played a most important part in determining the climate of our earth in past ages.— A general review is given of the modern status of eléctro-therapeutics.—Our readers are well acquainted with the intermite and its uses. A field in which it seems to promise particular usefulness is the repairing of dam-ages to sea going vessels. This application is described and illustrated in an article by L. E. Browns.—The lighting of the modern manufacturing plant is an issuportant problem, and not only from the point of view of humanity and sanitation, but also as a purely commercial consideration, in view of its direct influence upon manufacturing efficiency. "Making the Best Pos-sible Use of Daylight Hiumination" is the subject of an article dealing with this topic.—Prof. H. B. Dixon, working in conjunction with C. Campbell, reports on investigations regarding the effect of incombustible dusts on the explosion of mass.—Prof. P. Behrens writes on the Aesthetics of Industrial Buildings, that is to say, on beauty in technical structures, as determined by perfect adaptation to useful ends.—An article entitled "Our Life Blood" tells us many remarkable facts reparding a countrient of our body which is not only most important for life, but also full of inter-setting properties.—C. A. Battiscoule describes a very recogning scheme for exploiting the power of the tides.

—F. Campbell writes on Curiosities of Binocular

#### a Automobile and the Locomotive

The Editor of the SCIENTIFIC AMBRICAN:
On page 14 of your issue of July 5th is a photograph
is 100-on locomotive being towed by a 2-ton automobile. Let me call your attention to a slight mistake

The car in question is a Studebaker (E-M-F) "30," which is of 30 horse-power and not 40, as your story states. And in addition, the car weighed less than 3,000 pounds without its load.

THE STUDEBAKER CORPORATION OF AMERICA,
W. S. PETTIT, Advertising Manager, Detroit, Mich.

#### Lightning Prints

To the Editor of the Scientific American: I observe with interest a quotation in the Literary Digest talest from your issue of June 28th in which Charles F. takes from your same of June 28th in which Chaptes F. Takesan holds shas "lightning prints" res esimply tensor of the branch-like source of the discharge. My own observations tested to verify his statement, for I have seen those imprints upon horses and cattle killed by lightning on the buffsloopmen prints of the West in places where the encarest tree was miles distant and in some instance the wave necessary or other obligate than stank where there were no trees or other objects than stosi within sight. I have seen a number of variations of than "prints," and in many cases the hair was burned in dis-tinct lines down the animal's four legs to the heofs.

#### An American Coffee Made of Figs and Prunes

To the Editor of the Screwtric American: Relative to your article regarding the Feigen-Kaffoo of Austria, there is made in America, at Ran Jose, commercially, an article out of fige and prunes which is so superior to coffee that if people did not use the real onfise for the narcottle effect, it would entirely supplant office. The Harver is delicious and rich, the color fine. coffee. The flavor is delicious and rich, the color fine, and moreover it is even improved by warming over. Less is required than of coffee. It is a real food and rich in phosphorus. Of course, the advertising feature prohibits the mention of its name, but I did not like to have Austria carry off any honore in this respect when we have something better at home. It is really too bad for the health of the antion that the concern which manufactures the product does not exploit it outsides of a small local territory.

O. F. G. Dav. Minnescolis, Minn. Minnes

#### The Automatic Railroad Stop

The Astrometric Matterest Stop

To the Editor of the Scrawtrro America:

I have read with much inserest your article in your
issue of July 19th, estitied "The Competition for the
New York, New Haven and Hardord Railroad Company's Automatic Stop." This article affords a very
good idea of the great assuant of interest which inventors
as well as the general public feel on the subject of automatic train source. Research conversees in the mitroad
world immertably emphasise the importance of the
subheat.

revise manuscury empasses tan importance of the subbot.

One general impression, however, though held very widely, is eromeous, and this your article tended to enhance rather than correct. It is true that most of the derives and place that the mindled have been impressible. Nevertheless, sayous who has made a capital study of the subject knews that a namber of devices already offer considerable promise and that it considerable made produced in the power held with the control of the control of the produced interest of the produced interest in Mr. Religion. Statement, the reasons that control of the c

in the New York subway and elsewhere. The second kind is of the electrical type with continuous contact, using electric current picked up from a third rail. Of this type you mentioned two systems in the article re-

The third kind is also of the electrical type, but oper-aise by "wireless" or induced current. Probably the best example is that known as the Detroit automatic train control, a description of which is printed in the July issue of the Signal Engineer. It is to be noted that this device conforms to the primary requirement of the Train Control Board of the Interstate Commerce Commission to which as won state, the seven hundred Commission, to which, as you state, the seven hundred and four devices submitted in the competition failed to conform. In other words, this device is designed throughout on the closed circuit principle, so that the tarvugatur on the closed erreint principle, so that the failure of any part is self-detecting. Moreover, this system appears to conform to all the other requirements of the Train Control Board. An additional feature see span Control Board. An admindual resture of especial interest is that it may easily be equipped with the wireless telephone. It seems to be worth while to bring to the attention

of those interested in this important subject that the competition of the New York, New Haven and Hartford Railroad Company does not nece all the ideas of American inventors. all the ideas of American inventors. It is, therefore, not to be assumed that there exists no system that will minimize the serious disasters which ble F. McHENRY. our rails

#### Mr. Hanna Replies to Mr. Linton

Bit. Harms Replies to mer. Assesses
To the Rditor of the Sensitive American:
It was, indeed, not necessary for Mr. Grant Linton
to explain that the inascuracies in his first lotter on the
subject of Excible fastric serupisne wings were due
solely to a desire for eimplicity. Nor should it be necessary for me to say that this painfully excessive "simplicity" was what demanded my criticism. Simplicity
cosess to be a virtue when it degenerates into have
generalization. Aerodynamics is as exact science, and
it is not nossible to airly improc certain forces, how generalization. Aerodynamies is an axaot science, and it is not possible to airly ignoce certain forces, however slight, or advanged differences of direction, however slight, or say meety "an angle of insidence," without the least indication of what limits the angle may lie in. Such erouties will most certainly invalidate all conclusions. The proper place for Mr. Linton's simple theories was kis private note book, there to remain until be had developed them to an exact, concrete, and practical enough form for public presentation. The majority of the Schwitzer American's readers, I believe, here quite mifferent mental canadity to ae majority of the SCHNITFIC AMERICAN'S readers, believe, have quite sufficient mental capacity to imprehend a much more scientific and accurate pre-ntation of this fabric wing theory.

Aviation is, in these sad days, afflicted with too many Aviation is, in these sad cays, amiriced with too many recking-chair theorists, who rush into print with every wild idea that pops into their heads, and is bleesed with too few men of the type of Langley and Effet, who devoted their lives to proving their theories in their laboratories before talking about them; too few men laboratories before talking about them; too few men of the type of the Wrights and Blériot, who embodied their theories in actual nachines and proved them at the risk of death. God speed the day when the propor-tion shall be reversed! A full half century ago there were almost as many men with impractical flight theories as there are now, but it was not until the coming of

con same or every set of the many sense that we seem are now, but it was not until the coming of meas strong enough to put good theory to actual test that flight become a reality.

However, I do find it necessary to defend myself from unjustifiable misquoisation. I did not, as Mr. Linton sessers, "confess ignorance of the truth of his statement that in both classes of vehicles the best efficiency could only be altrained by altering the length of the obord." My actual words in the issue of May 10th, page 421, are pisla enough. And to this day I have not heard anyone of sormanical standing assert that increased efficiency could be attained only by lengthening ar shorieting enough. And to this day I have not heard anyone of sormanical standing assert that increased efficiency could be attained only by lengthening ar shorieting enough. And to this day I have not heard anyone of sormanical standing assert that increased efficiency could be attained only by lengthening archiveling entry in the size of the second of I snow, of any and designed to change its width from mast to outer edge, that is, its chord. To be sure, if a sail bage out to a deeper entry, fix shorted will decrease slightly. If Mr. Linton means that the heat efficiency san only be obtained by to changing the sembler of the places, why did he not say so? I would suggest that be looked appartment of Measure. Munn & Co. can supply him with a modern diotionary of servicential terms. It is by no measure measure. Munn & Co. can supply him with a modern diotionary of servicential terms. It is by no measure measure. Munn & Co. can an astrophage what for increase the cumber, or rice series. It is been the British plants (Mr. 16,06), 11010 to Smault-Publisher for a wrige of variable camber.

I must be the British plants (Mr. 16,06), 11010 to Smault-Publisher for a wrige of variable camber.

I must be the British plants (Mr. 16,06), 11010 to Smault-Publisher for a wrige of variable camber.

I must be the British plants (Mr. 16,06), 11010 to Smault-Publisher for

than in the design of the sailing yacht," he ought, to than in the design of the sating years, we ought, to be consistent, to put a little more exquisite and scourate detail and less vague and inexact generalization into the exposition of his theory.

Again, I did not "assume that, because the upward

component of the air pressure is uniformly distributed over the surface, the total air pressure is likewise," as Mr. Linton asserts I did On the contrary, I denied such a possibility, and cited Eiffel's experiments as proof. My attitude was so clear that such a glaring mis-statement is difficult to understand. Pictures are generally easier to comprehend than written descrip-tions, so I would suggest that Mr. Linton may best secure his first knowledge of the actual conditions of sir pressure around an inclined place by consulting excellent graphic charts of Eiffel's pressure measure-its that Mr. E. R. Armstrong gives on page 418, vol. iv. Acro and Hudro.

I am afraid Mr. Lanton is jesting when he proposes to subject the two sides of the fabrue to the air flow singly. For certainly the unbalanced force on one side would deform the fabric out of all possible wing pe, and if by any complicated apparatus this result ild be avoided, the conditions would still be wholly different from those of actual flight, and consequently the data obtained would be useless. The lift of a plane is not only dependent on the pressure below and depres-sion above, but on the extent to which these two simultaneous forces are mutually neutralized and destroyed

around the edges of the surface.

I still think that the belief in the parabola as the only correct basic curve for wing sections belongs to the past. The only authority for it Mr. Linton cites is Montgomery. I could name a dosen others, but they are all, like Montgomery, men who theorized in the days before acroplanes were living, everyday reslities, disproving with monotonous regularity one after another our preconceived mathematical theories, such as Newcomb's proof of the impossibility of mechanical might and Navier's mathematical proof that one swallow required one seventeenth of a horse-power to fly

I was aware of Major Reber's comment on the regular d of Vedrmes in the last Gordon Bennett race, speed of Vedrines in the last Gordon Bennett race. But we cannot judge aviation as a whole by the per-formance of one highly specialized racing machine. And I am quite sure that Major Rober himself would never sanction the purchase, for actual army use, of any acroplane that could not show a much greater speed range than this Deperdussin racer did or could

The most absolutely ignorant and erroneous statement of Mr. Linton's is this gen. "Though the ability to vary the speed of horizontal flight within wide limits to vary the speed of nonzona lagne within wide units is a most desirable quality of the aeroplane, 'this feature (as attained at present) is only a proof of poor design, or at least of inefficient running." I must gently but or at least of mefficient running." I must gently firmly decline his offer to inform me that "the bip is by no means acknowledged the most highly specialized type of the heavier-than-air machine." The biplane has been developed as far in its sphere as the monoplane; it is a type that is here to stay; and it is, for structural reasons, the type of the large unchines of the future. It flies by the same processes, and obevs the same laws, as the monoplane does. Consequently, facts proven by it cannot be ignored. However, if anton prefers data derived from monoplanes, 1 call his attention to the performance of the Hanrict, Blériot, Bristol, and Deperdussin monoplanes in the British military trials These machines showed speed ranges of 25, for cent, 47.3 per cent, 25 per cent, and 26 per cent, respectively. To take a more recent instance, at Villacoublay, on June 21st of this year, des Moulinais obtained a speed range of bottom of the Moulinais obtained a speed range of bottom of the Moulinais obtained as speed range of bottom. monoplane, while (lilbert, with a 50 Rhone machine of the same make, obtained a range of between 4134 and 7334 miles. In every case these ranges were the product of the deliberate efforts of some of the world's ablest designers and pilots. Mr. Linton should be familiar with the experiments to increase the speed ar with the experiments to increase variation of a Farman biplane which the National Physical Laborator of England has just concluded as successfully. Does he access that honored insti-tution of poor design? The fallacy of flexible fabric, whether for actual wings

or as a means of ascertaining the best wing curvature. is at once evalent if we will remember that the object of a wing is to deform the air in the manner most adus to us, rather than to permit the air deform the wing in the manner most advantageous to it. Anything that favors a certain motion must necessarily be unfavorable to the equal and opposite reaction.

In these two letters I have said all I care to on the

subject, and I believe that Mr. Linton has made nosition clear also in his two letters. I suggest, then, position clear also in his two letters. I suggest, then, the case should now be placed in the hands of the jury. Let us have, through the columns of the Scientific American, the opinions of others, perhaps better qualified to judge than either Mr. Linton or myself.

Galveston, Torga. John G. Hanna.

# Buying and Selling Silver and Gold

The Scientific Side of the Assay Office at New York

By H. J. Slaker

THE public has practically two relations to the Assay Office at New York; first, that of selling gold and silver to the Government, and, second, that of buying both of these metals from it. With some exceptions,

the Government buys any amount of gold from any individual and page \$20.07 an ounce for the gold contents. If the deposit contains silver also, it is either paid for at the market price, or its equivalent in fine silvers is returned to the deposite.

wer is returned to the depositor. The purchased deposit may represent the product from a mining company, dental scrap, an import of gold from Enrope, or discrated jewelty. If the fewelty could tell its history, one might bearn many a story of poverty and proken pride, for many times old family helricoms, or even interole emblems, in chased gold and silver, are handed in at the window of the Assay Office. The very day these deposits are received they lose their identity, for they pass immediately hird a cruelile, are melted and cost into the form of an uniliteresting ber. The Government accumilates a great variety of sizes of bars, having many different finenesses.

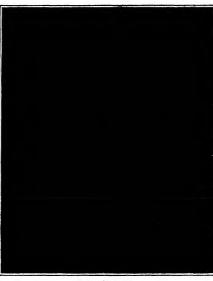

When the justile wishes to buy gold, it demands its product satisfies the every particular for the various trades which utilize this metal, and the high gride metal produced by the Government meets these demands. It may be the dental profession wishes material for filling teeth, in which case an exceedingly high grade gold is desired, since a trace of lumprity latter-frees with the cold welding. Or again, the gold beater's husdiness demands metal close to absolute jurity, so that the leaves may be isomeded to an exceedingly great thinness. The Jeweel'er strade is not a fastise of the control of the

from the public and the selling of pure gold to the public, there is necessarily a series of operations, which is known as refulng Several different processes of refulng have been in use, all of them open to some objection, such as fumes, great cost, or excessive loss of the precious metals. The electrolytic method, after an extended test of several years, has b installed in all the Government refineries. In principle, this is a plating process very much resembling that of sliver and gold plating, with the exception that instead of a smooth deposit, which appeals to the eye, a deposit of quantity and purity is obtained. In actual practice the anode is a bar made from the different deposits, sultable in fineness and form for the process, while the cathode is a thin strip of pure metal upon which the deposit is anthered and is of the same metal as the deposit So long as certain conditions such as voltage, strength of electrolyte, etc., are kept constant, nothing but the desired metal will be deposited. Port of the duties of the working force is to keep

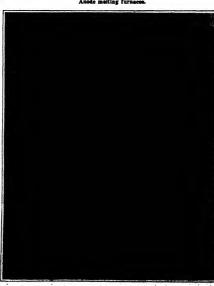

The operations are divided futo two parts, known as silver retining and gold refining, and while they more or less overials, they will be considered in this order. Silver Refining.

Practically all deposits under 900 fine in gold are sent to the silver refinery, while those above that go directly to the gold refinery. The silver anodes (3 inches by 16 inches by 8, inch thick) are made directly from the deposits received over the counter and are alloyed to one another so that the resultant melt will be kept within the following limits: gold, 250 to 400; base, 128% to under; and remain-

ing parts sliver. To keep within the limits mentioned, this selection of the various deposits requires much patience, because of the great variety of the weights and finenesses, but by constant practice one becomes expert in this detail. The necessity of bandlings

Anode melting furnaces.

Dectrolytic said cotts.

much as 150 parts base and also such a large partion of gold makes the electrolytic method difficult. cupeling treatment has been suggested, but the low of gold and the great values tied up in formaces are to problibit this. Each anode is put into a musical

tied at the top and suspended is the altrolyte by means of a small seek his The hook passes through a hole small the time of casting, in the top of anode and is hung over the condured. The conducting rod is companied a hard rubber tube reinforced chavitan is center with cold rolled steel. The altric current is carried by means with this strip of silver which is half-round over the hard rubber tube and fastended tape at each end. It will be noted that both gold and silver are used to early suirent; this is because they give good content and not corrode.

The cells (brown stoneware, 2 feet by 4 feet by 2 feet deep) are arranged in two sets of streen in series, placed close together on scapsions slales of proper height The eighteen supporting rods for each cell are spaced 2½ inches spart and this distance is maintained by hard ruber separators placed on the rims of the cells. Each supporting rod is double the width of a cell, so that one rod expende over two cells and serves the purpose or an anode support in one and a cathode support in the next. This plan slower the cells are the next this plan slower the cell, carrying a total of 43 anodes and an equal number of cattode rods for each cell, carrying a total of 43 anodes and 43 cuthode uniformly distributed. A glass propeller in each jar, driven by a motor-operated belt, gives the necessary circulation to the electrolyte.

The electrolyte contains 3 per cent

The electrolyte contains 3 per cent silver nitrate and 2 per cent of free nitric acid, and this strength is maintained by adding either acid or silver

The action of the electric current is interesting, for in passing from the anode to the electrolyte, it dissolves diver and bases mental, leaving gold in the bag as a coherent apongs mass; and again in passing from the electrolyte to the cuthode, the electrolyte to the cuthode, the electrolyte and plates out nothing but the silver. Thus a satisfactory separation is under between silver and gold at the nuclea and between silver and base metal at the cathode, while all the component parts of the original guade are in a state to be relatively easily regular.

Every eight hours each cathode is lifted out and the loosely adhering aliver crystale are accepted into a vat, washed, and then intelled into merchant bars for the trade. This is the fine aliver product of the refinery. Some of these crystals fall to the bottom of the tank and are regained at the time of the removing of the electrolyte. If the measurary care is exercised, the result is very merty pure silver, not containing more than a half part in a thousand of foreign metals. The gold contents of this deposited either are watched carrelly and not allowed to exceed two parts in a hundred thousand. Just how this gold flood is tway into the silver is mixing the production of the silver is mixing the product of the silver is mixing the product of the silver is unknown, but it is believed it is introduced mechanically, rether than chemically or electrically. However, said, platinum wise palasitum can be found in the foul electrolyte for exceedingly small simounts. On account of the requisity which the electrolyte becomes fool and the necessity for "sewring", the Prognastity, abard rother constributed "pump sensores the actions, of the freeze, it is freeze, it is

come metals which are precipitated by it in the form of stillne, which is washed, melted and passed through the electrotytic process a second time. The solution their which the after has been precipitated is allowed so rein of to the sevier. The low current density of weigh amperes per square foot is used in order to pre-regar the been metals from plating over with the sliver, and also in order to obtain a more cobert erystal form.

est irrystal form.

When the spongr anode gold is 'remoyed from the bags the aliver has not been doughedly extended by the spongramed from the bags the slower than the spongramed from the platform and palledium remain with the gold and are regalated further along in the process.

The gold which comes from the anodes of the silver refining, tower with the gold to the comes from the anodes of the silver refining, tower with the gold which comes from the anodes of the silver refining, tower the with the gold which comes from the anodes of the silver refining, tower they will be gold to the silver refining, tower the with the

of the silver refining, together with the gold in the original deposits which are goan in the original deposits which are high enough in fineness to be suitable, pass through the gold cells. These cells (14 inches by 19 inches by 12 inches deep) are Royal Berlin porcelain because this wate withstands the chemically active electrolyte. The general arrangement of the gold cells and the conducting rode is mewhat similar to the sliver system se hard rubber rods are covered with s thin strip of gold for carrying the current and the circulation is obtained by hard and the circulation is obtained by hard rubber propellers driven by a motor. The electrolyte is composed of 50 grammes of gold as gold chloride to the liter with some free hydrochloric acid. The anode (8 feet by 3 feet by 4, foot binks) is slightly wedge shape in order to prevent the bar from being eaten off near the sur-face. The portion which remains above the solution has a hole near the top, is reduced in thickness and has corners cut reduced in thickness and has corners cut off. The silver contents of the gold anodes, if above 5 per cent, form an insoluble silver chloride conting which pre-vents the solution of the anode and stually gives off chlorine gas.

It becomes necessary to remove this coating either in some mechanical manner, as scraping by hand, or by an electrical device. The latter device is now ing used with a fair amount of succe

An alternating current is run in series with the direct current, the resultant wave being a pulsating current through the being a pulsating current through the ceils. Its principal effect is to keep the anode clear from the insoluble silver chloride, but it also issuess the amount of free hydrochloric acid necessary and re-duces the amount of gold in the slimer. An effective current density of 70 amperes per square foot is maintained, which is increased if a higher anode fineness is us

There are four sets of twelve cells each laced upon sometimes slabs at a convenient working height.

The slimes and the electrolyte contain all the metris which were in the anode, and it is in this solution that most of the platinum and palladium gradually accumulate. When the solution becomes foul, the platinum is precipitated by sal-ammoniac as platflum ammonium chloride.

An excess of sal-ammoniac is used and the surplus serves, after an oxidizing treatment, to throw out the paliadium. The solution from which the platflum has been recipitated is syphoned into a clean jar and some potassium chlorate with a small amount, of potassium permanganate is added. This throws out the red sait of palledium ammonlum chloride.

The by-products of platinum and palle-dium are sold to the highest bidder and the proceeds are added to the United States Treasury.

The silves are washed and the silver chipride reduced by metallic sipe, and after adding a certain amount of allver they are cost into anodes for the allver cells.

ding to's large settling tank in the basoverflow Fundang to a major menting task to appear this system of traps practically insures against a many market which run to the sewer to be free from value. The pressure blower system which gives air to all the furnace, in the building, and has given perfect satisfaction, is rather different from that somerally in use for similar purposes. It is known as a centrifugal compressor and has a rotating element mounted upon the common shaft with the driving element of the motor. This eliminates all gears, belts, chains, etc., and the compressor runs the same speed as the driving The air pressure is constant through all loads and the power consumption is proportional to the load.

The melting room of the meiting and refining department has eight standard oil furnaces arranged around a square, and with the necessary tanks,

pans and benches, furnish the equipment of the room. The square, which is in the middle of the room, is built of firebrick and so constructed that it constitutes a settling chamber with the outlet leading from its center to a large fine off to one side. The flue is vertical and connects all furnaces throughout the building to a large settling chamber on the ninth floor. The construction is such that all fines and ing chambers can be easily cleaned and the values obtained from the dust.

The standard furance is so built that the burner looks directly down in the combustion chamber, which arrangement puts the blow torch flame against the bottom firehrick instead of the crucible, as is usual in many of this type of furnace.

The make-up room and office occupies the other half of the third floor and contains the necessary working desks, iwo large scales, one long table with stone too covered with teather, and the working vault. The vault has a lowering platform before the door, which allows the floor level of the vault to be the same as the room. The vaults throughout the building have the same construction, and this has proved to be of great value because it allows the heavy trucks to be wed in and out easily

The sixth floor contains the shop and the electrical dynamos for producing the proper current for the refining cells, the witchboard and controlling devices The three low-volinge machines are separately excited from an outside source and are so connected through the switchboard that any machine can be used on any circuit. The nuchluss ure duplicate, and each is capable of producing 1,200 amperes at volts, but only one is run ut u timo.

The third machine was specially built to produce the pulsating current by placing an alternating current in series with a direct current. This is accomplished by mounting on one bedplate four machines, a driving motor, a direct current dynamo. phase atternating current dyusme and an exciter. One lead from the alternate passes directly to one lead of the direct current machine and the other two leads go to the gold cells

The controlling device is unique because of the fact that the 110-volt exciter ex-cites the fields of both the alternator and the direct current machines, but with a ud rheostat in series with each, thus allowing a relative adjustment of votinge The fields of the exciter itself are excited by an outside source through an adjustable rheostat This complete arrange gives the necessary large range of nd-justments to suit every condition that might arise. The value of this combina-tion machine is, that it allows the use of es containing a greater proportion of silver, does away with the necessity of heating the electrolyte and makes a slime containing a less quantity of gold

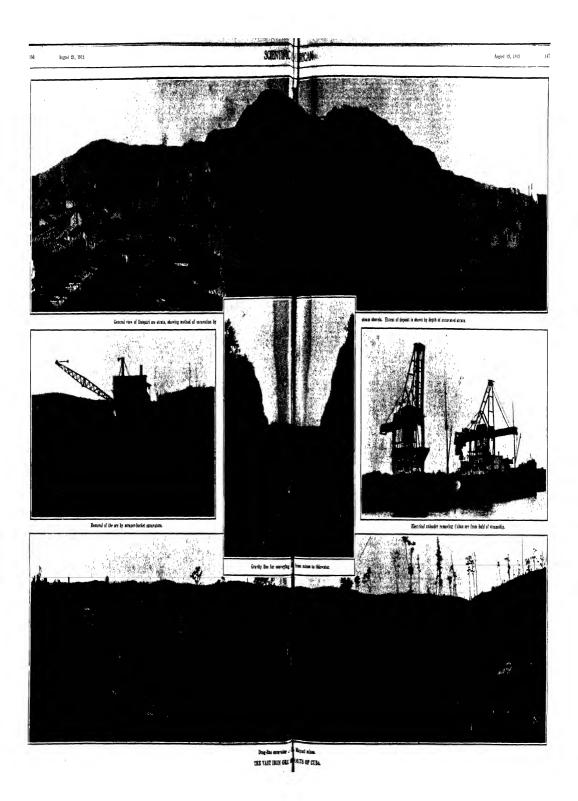

The low-voltage dynamos have a graphite composition brush and a device that gives a series of end thrusts on the end of the shaft, which prevents the brushes from wearing tracks in the com-

The shop proper contains a lathe, drill press, shaper, emery and grind stone and several smatter muchines, all of them operated by individual motors. The rolls for making cathodes are located on this floor and are driven by an atternating cur-rent motor. The idea has been to place

all possible machines on the sixth floor so out of seld fumes, and this plan has given all that was expected of it.

The seventh floor has been given over to the silver cells and the precipitating tanks for the foul electrolyte. There are two circuits of vertical cells, each series containing 16 jars placed on a long table built of brick topped with soapstone slabs. The slabs are counter-

#### Expanding Socket for Screw Spikes By A. R. Marrison

TN order to provide a better hold for screw spikes in rational ties, a Parisine engineer has recently invented an expanding socket. The socket consists of a metal tube threaded both within and without. The socket is slit at the lower end to about balf its le so as to form four arms which may be spread out by acrewing the spike in after the socket has been acrewed to the wood. Thus the socket is firmly anchored in the tie and affords a far betier grip for the screthan can be obtained by acrowing them directly into the wood. At the top of the socket are two diametrically opposed notches which serve, like the slot in a head, to permit of screwing the socket into place, The socket must be placed as close as po The secret must be piaced as close as possible to the edge of the rati base and so the exterior thread is de-lermined by the thickness of the base flaure.

As shown in the section, the depth of thread on the

inner wall of the socket is not uniform throughout. At the lower part the projection of the thread gradually increases without however clumping the pitch. When atting the sockets into new wood, a hole is first bored e necessary depth and tapped, after which the top of the expanding socket is fitted with a mandrel an the socket is then screwed home. As the lower part of the socket is slit, the arms will converge, as indicated in one of the sectional views. However, when the screw spike is screwed into the socket the arms will be forced out, as shown, anchoring them firmly into the wood, so that it will be impossible for the socket to be pulled out. In old ties where the screw spikes have been torn out, in our ties where the serve spaces have been corn
out of their holes, or the wood has decayed, it is merely
necessary to enlarge the hole, and tap it to fit the expanding socket. Old serew spikes can be replaced in
tals way right on the track without having to move the rail or the tie

# A New Neiseless Gear for Motor Cars All almost a year a prominent automobile manufac-turing company has been conducting a series of beets and experiments in search for a type of sear that, would prove both notehess and efficient in opera-tion. principally a rolling one. After a certain amount of principally a rolling loss are wear the spur or bevel gear becomes noisy on account of the backlash. This, however, is claimed to be entirely eliminated in this latest type of gear.

In the accompanying illustration the worm bevel gear shown installed in the rear axle housing in preci the same manner as the usual type. Very little differ is noticeable at first glance between this gear and the older one, although on closer inspection it will be on that the teeth of the worm bevel are curved, as are to those of the plains which is hidden from view by

#### A Gyroscopic Mechanism for Recording Roll and Pitch of Vessels at Sea

N a recent paper before the Society of Naval Archi-I tects and Marine Engineers, Mr. Elmer A. Sperry mentioned in a more or less casual way, a device which had invented for recording the rolling and pitching sels in a seaway by means of gyroscopic oechan-

ism. The device is so extremely in gentlous and efficient for the purpose designed that it is believed to deserve more than the mere mention modestly a c-corded to it by its in veotor.

In attacking the prob lem of the prevention of rolling and pitching of ships it is evident that we can go at it more hetelligently if we are able to determine in the first place, exactly how much the roll and pitch of various types of vessels is it is also plulu that la order to measure accurately the

roll and pitch com-nents proper it is necessary to eliminate as far as possible all motions relating to vawing, azimuth move ments and other movements of short periods due to outside influences acting on the shin

"Universal or compound angular motion may be said to be made up of three primary components sindiar to to be inade up of three primary components sindiar to the three primary components of while light and prob-ably from the same basal cause, thus universal augu-lar motion may be resolved into motion about three axes, all normal to each other and bearing the relation of the three converging margins of a cube. Gyroscopes mounted for producing motion records, so far as has been heretofore published, are in each case critical to all of the three above named components. In this manner the rolling record is liable to be fulsified by mottons which really have their origin in yawing. or pitching, or both.

The problem then consists in so mounting a gyrostone as to nake it critical to only one slugle compopent of motion and at the same time to make it have very long natural period as to be entirely removed from any influences of the comparatively short eriods of motion on the ship itself.

periods of motion on the ship itself. This the investor has succeeded in doing in the apparatus shown in Figs. 1 and 2, and by means of a set of ingeniously mounted pencils we are able to record the curves of rolling and pitching for any vessel with a black degree of accuracy. The recorders shown consist essentially of two sets of gyroscopic pendulums, one for recording the roll, and the other pendulums, one for recording the roll, and the other for recording the pitch, and to give the reader a con-crete idea of the qualities of the pendulums it may be stated that they actually represent (due to their high speed of rotation) a weight of 1½ tons hung from a point 10 miles above the earth, thus having a practically infinite period of oscillation. It is by means of this very long virtual length of pendulum that there has been elinduated in the records practically all influences of extraneous motion except that of the one selected component of the motions of the ship, such for example, as the rolling or the pitching.

As may be seen from honecting the photograph, the capitance consists of two sets of gyra wheels, two wheels in a set, about twenty pounds in weight, mounted within a case performing the function at once of a support for the wheels and the precession ring. These wheels are electrically driven by a 3-phase mo-tor mounted within the frame of the machine so as to give to the wheels practically the same speed.

wheels of either set spin in opposite directions and further, precess oppositely, the precession frames being coupled for opposite and neutralized precession There is seen mounted be the lower part of the frame a There is seen mounted in the lower part of the France a motor generator set which receives 125 voits direct cur-rent and delivers 3-phase alternating current. A low electric motive force is used on the A. C. side so that all points of the apparatus will be harmless from the

The spinning gyro wheels are mounted in elliptical stabilized rings supporting the gyro cases on parallel axes, and these in turn are pivoted at right angles to the main frame of the apparatus. The stabilized base the main frame of the apparatus. The scattises may frames are seen to be normal to each other, one responding to all the components of the pilich of the ship and the other to the roll of the ship, and they are prac-

# The Ten Greatest **Inventions of Our Time**

We hear much of the great inventions of the pastthe telegraph, the sewing machine, the telephone, the reaping machine, photography, Bessemer and open hearth steel, the steam engine and the phonograph. Yet the inventions of our own time are as epoch-making and as dramatic as these.

Perhaps because we have become accustomed to the use of the old machines and discoveries, perhaps because the achievements of latter-day inventors succeed one another so rapidly that we are not given much time to marvel at any one of them, we have not fully realized how stirring and wonderful are the products of modern ingenuity.

Only five years ago the man-carrying aeroplane made its first public flights; only the other day hundreds of passengers on a sinking ship were saved with the aid of wireless telegraphy. At least a dozen inventions as great have been perfected in our own time, and all of them have made a man's work count for more than it ever did before, and have made the world more livable than it ever was.

Why should we not tell the story of our own deeds? Why should we not review the industries created by men who are still living, men whose names will go down into history with those of Watt, Morse, McCormick and Howe?

Tha was the underlying idea of the November Magazine Number of the Scientific American. We knew that the "ten greatest inventions of our time" was a big subject when first we planned the number, but how big it was we never realized until we surveyed the field of modern invention.

Then we saw how astonishing was the progress made in our own day, how much mankind had benefited by the inventions of great modern intellects. We began to appraise inventions, to weigh one against the other, and to determine in our own minds which ten had contributed most to human progress and happiness, which were really great pioneer inventions, and which merely remarkable and valuable improvements on successful past conceptions. There were so many achievements to consider that it was hard to arrive at a definite conclusion.

The upshot of our own thinking has been to leave to our readers the decision

# What Are the Ten Greatest Inventions of Our Time. and Why?

For the Three best articles on the subject, the Scientific American offers in the order of merit, three cash prizes:

First Prize: \$150.00 for the best article Second Prize: \$100.00 for the second best article Third Prize: \$50.00 for the third best article

#### Teaching from the Child's Point of View

and from page 141.)

ot add to our knowledge, though he is cile in new combinations, and in any facile in new combinations, and in any case, only that man can be original who can cut himself loose from current associations. He says that there are the sys-tematizers and critics, predominantly synthetic and analytic, respectively, but the highest degree of intelligence possesses great power in both synthesis and an-

In his study in connection with the intelligence of over 800 pupils Meumann found that not infrequently very bright found that not intrequently very origin school children show a slow immediate reproduction, whereas less intelligent pupils exhibit a quick and fitful repro-duction, showing less capacity of mental effort, and indicating less attention to the content, together with a tendency to ward iess resistance in reproduction. He concludes that wealth of imagery

and originality of reproduction however, any departure of the subject from the type proper to his stage of the ent, are characteristics of intelligence. Dull pupils reproduce, e. g., wore frequently named together, and depend much on what has been learned at school for the material as well as the form of crete as that of the bright child. pupils also use verbal imagery to a larger extent than bright pupils, thus tending to approximate to the adult type of thinking and consequently appearing in this regard precocious. His results show that the degree of mental development of puntly is excertained by their capacity of abstraction, and can be recognised by their retention of abstract words, since such retention is mainly dependent upor their ability of understanding the words He asserts that the positive relation be emory and general mental pro iency of pupils is very striking.

On the basis of the present writer's experiments in the Zürich isberatory popular notion that the child's memuperior to that of the adult, because the experiments show that the child nee re time and more repetitions in n Thus, an adu izing than the adult. seded 10 repetitions to mer nse syliables, and a school child needed 63 repetitions to memorise the same series. Of course, there is a fall-ing off after maturity in the capacity to learn new and disconnected facts, but this inability must not be taken as a characteristic of anything except the con nt of the disabilities of age.

#### A Scientific Study of Children.

In his tests of the memo children alone and when working together e found that the class-room distu influences (the noise of writing, walking about, whispering, the sight of the move ments of the pupils, the occasional word of the teacher, etc.) have no special inof the teacher, etc.) have no special in-fluence, i. e., the pupil shows better re-suits if he works together with other pupils in the school than if he works aione, isolated. These differences in memory for the individual and the common test were strikingly large in cases of th younger children. One day he asked a number of the pupils in case of the in-dividual tests whether they would prefer such exercise in the class or alo cent of the pupils gave the decided answ that they would prefer to do the work in the class-room. In one other experiment tested repeatedly a few 13- or 14-year old-pupils with the dynamometer and his ergograph, and found that in the case of the tests of the pupils separately, with no one else in the r m, the quantity of work was always less than when the

others were present.

In many other of his investigations of the pupils he found great and interesting the pupils he found great and interesting individual differences. But he does not want to push the doctrine of individual differences in pupils to the extreme, be-cause we should thus maket a useasce of education impossible, for estauce usunot

#### Buying and Selling Silver and Gold (Concluded from page 145.)

sunk, making a 16-inch rim around the whole table, thus preventing drops of the electrolytes from falling on the floor. The floor of this room, and the eighth, or gold, noor of talk room, and the eagach, or good, room is made of soapstone slabs, so that any spill of acid or electrolyte does no harm, A centrifugal hand rubber pump lifts the foul electrolyte from the level of the cells to that of the precipitating tanks and for this purpose is much superior to the reciprocating type, as there are no-valves under which small pieces of for-

which, with the exception of the sweep cellar, completes the plant. The gold cells are set on soapstone topped tables. There are two tables, each holding two sets of twelve cells, with a heavy scapstone divid-ing slab through the middle. On the top of the dividing slab, electrically driven runs a light shaft line with pulleys at proper intervals. The propellers are caron wooden arms bolted to the central slab and are driven by a light belt from the shaft line. In cleaning up, the entire top of the cell is exposed, thus riving the man in charge ample space for lifting out anodes and slimes. A large soapstone hood with wire reinforced glass for sides, gives the proper facilities for the treatment of platinum and palladium

A testing laboratory is partitioned off from this floor, in which all the foul solutions are tested for values before they pass to the sewer. The different electrolytes are tested for their strength of acid and metal values and also any nece experimental work done.

The sweep cellar has been put in opera-tion recently and its equipment consists of a jaw crusher which crushes the sweeps to one inch or less in diameter, one mill with 60 mesh screen which grinds the sweeps under water until they are the Hubber Grower's Association will con-enough to pass through the screen to the duct a series of six contests, offering two settling tanks, and a steam drise; prises as follows: First, medals for the The type of unit to a series of the contests. two settling tanks, and a steam drier.

tically free from response to all other ents of motion

The rolling and pitching records are nade upon two rolls of paper six inche in width driven by the same small moto at the same rate. There is also provided a means of marking the seconds on the record, and the center or base line from which it can be determined to which side any particular roll was made. The leve of the records is about four feet from the ment is self-contained and portable. Some idea of the extreme accur-

the apparatus can be obtained from the following report of a test: The vessel on which the machine was mounted was floated in the bottom of a dry-dock, the water being drained down to 18 feet. The w ther conditions were excellent, with prac-tically no wind, and the vessel was al most entirely protected from any outside influences by the sides of the dock. There were used three plumb hobs on lines 121/2 feet long, the bobs being submerged, and the movement of the pencil was constantly checked up by the lines. The vessel was under constant motion and every motion was perfectly apparent and could be eastly recorded. Whenever the boat settled to an extremely small fraction of a de-gree of roll, the center was determined with great accuracy and it was found that at no time had the gyroscopic pendulum of the apparatus moved a hair's breadth This was further corroborated by the position of the levels connected with the pendulum. Interest, of course, centered upon the return of the datum point at the end of the test, and it was fo the pendulum returned to within less than 1/64 of an inch of its original position It was first thought that this was an error of the apparatus, but upon comparing results it was found that the the proper action of the machine.

The eighth floor contains the gold cells, with the redding of the groscopic re-

#### Large List of Prizes in 1914 Rubber Exhibit

THE fourth International Rubber and Allied Industries Exhibition, in conjunction with the first International Corton, Fibers and Other Tropical Products and Allied Industries Exhibition, is to be held in London from June 24th to July 9th, 1914. The object of the exhibit, like that of its predecessors, is to promote trade and commerce with all rubber-pro ducing and consuming countries, as as to bring together producers, manufac turers, chemists, sele rubber products both crude and manufac The exhibition will permit of the display of the principal commercial products of rubber grown in the soil, as well as manufactured products, machinery, and appliances. Many of the British and foreign governments and associations have already expressed their willingness to being represented in the various de-

partmente One of the most important fe the announcement is the offer of a large number of prizes to exhibitors in the dif-ferent departments. The committee of the best come sheet and assorted grades of plantation rubber; second, a gold medal for the be exhibit connected with plantation rubb grown in the middle East; third, a pris-of 460 (\$250) and a gold medal for the nost valuable improvement most valuable improvement with the collection or preparation

#### A Costly Lack of Co-ordination

OW absolutely necessary it is to lay out and execute manifelial limitovements of an engl neering character upon a carefully thought out to ordinated plan is strikingly limstrated in the ease of the three great bridges which have been built during the past eighteen years across the East River, These mounmental structures, the the boro Cantilever Bridge and the Williamsburg and Man luttun Suspension Bridges. The two hist numed being the greatest structures of their kind in existence rep resent together a draught moon the city's trought of over \$72,000,000) Nevertheless, not one of them is to duy being utilized to its full capacity, and two of them day being utilized to its init capacity, and two or seem at lens). In spite of the fact that they have been com-pleted for several years, are not even vet performing their principal function as links in the rapid transit system of Greater New York - Indeed, it is only within the last few weeks that a stretch of four track subway, built to form a loop connection between two of the three es, which has bin idle for severni years, has been part in partial operation, with two of its four tracks in Furthermore, it must be several years before the Queensboro and Manhattan Bridges, representing an investment of about \$50,000,000, can be brought into full service us parts of the rapid train

Such haphward and grossly extravagint methods in the conduct of mindfull at farge is without a parallel, and the student of citic management knows not wether to be more anomalous of at the political conditions which rendered such wild extravagince possible, or at the fundant stubility of a city that could stand this tremendions study in min its recorress.

The construction of these engineering white elephants of for such they have been for a number of yours—was entered upon without my comprehensive view of the transportation problem, or my intelligent conception of their proper role as forming part of the city's thorough are the city's constitution of the city's thorough are the city's city and city are the city's city and city are city are city are city and city are city and city are city are city are city are city and city are city are city and city are city are city are city are city are city and city are city

The city is growing by leaps and bounds," said the city futhers of those days, "the present transportation facilities are landsquarte, the people in increasing numbers wish to pass from Long Island to Manhattan, the East River is an obstacle, let us build bridges." And the hidges were built

The most that can be said in extensation is that it was not understood then so clearly us it is today, that such great bridges can resultie their fail mechanics only if they form sections of the important avenues of rived. It is understood to high that trifuge terminals are a inistake serving, as they do, to promote congestion at specified points. Traffic should downcross in bridge with us much freedom as it does through any broad avenue on solid ground. The planning of great bridges should be done contemporaneously with the planning of facilities by which the various means of travel traffey, elevated, or sulvey, will be inbe to make full use of them on the very day of their objecting. Thunks to the good work done by the Public Service Commission and the Board of Apportunement, the East Bleer bridges have now been brought but their proper relation to the vast extensions of our sulveny systems which are under construction, and before many veries have passed it be probable that these grand confinering works will be rendering a service to New endsheering works will be rendering a service to New

York city proportionate to their great carrying capacity and the chormous sums spent upon their construction.

#### Wind Pressure on Ocean Liners

FEW vector ago, we offered the following problom for the consideration of the readers of the Scrievitte America. "The largest transilantle liner now under construction will present to a bend wind a cross-sectional area above water, including smokestocks, musts, etc., on hour 0,500 square feet. If the ship were steaming at a reduced speed of 15 whote against a bend wind of 66 inlies velocity, how much horse-power would be necessary to overcome the wind pressure alone?"

We offered thu problem in the conteilon that the majority of our restors in all title conception of the heavy draught in it is made a just the effectly hones power of a lace ship to meet the redshire date to while presents about a happrosolal which is coullrased by the fact that the majority and the majority and

meet in manage the extending of what redstance has both a popular and academic interest, and that it is of serious economic hapstance will be molested when we state that our lavestigation of the problem shows that in a transituate liner of the largest size, say of 100 Ferd beam, 150 Feet length, and, let us say, 60,000 horse-power, no less than 20 per cent of the horse power or ulmost 12,000, would be consumed in overcoming head-wind resistance when the ship was steaming in 15 knots, against a 65-mile gate—and we believe that this estimate is, if any-thing, rather length unmount

that correspondence with several navial authorities here and alroad despens the convertion that here is an element in the proquision of ships and particularly of the glant ships of to-day, which has useer received the actual time of to-day, which has useer received the careful investigation which its Importance demands. Thus, a beading authority on modet tank investigation writes us. "The question of the air resistance for ships has never been solved with great accuracy so far as I shaw," and our answers from avail methicets vary all the way from "compared with the water resistance, all resistances is of comparatively little importance" to the statement "in the case of ships of the size of the "importance" is much as one third of the hove-power night be consumed in overcoming air resistance in a heavy solo."

Fundamental to the problem is the question of aniressure per unit of surface over large areas such as are here considered. Some thirty years any, when its healpanin taker was destining the Peruli Bridge, he found himself saddled by the British government with a unit pressure of 50 pounds per square ford—a fact which should temper judgment with merry on the perof those critica who complain of the nuncescary weight and bulk of the structure. Our own American Society of Criti Burdineers has compromised on thirty pounds, per square foot, as a basis on which to design the windscript of the structure of the peruling of the windscript of the structure. Our own American Society of Criti Burdineers has compromised on thirty pounds per square foot, as a basis on which to design the windscript of rocks, bridges and tall buildings. One navial authority tells us that he would assume not less than authority tells us that he would assume not less than authority tells us that he would assume not less than authority tells us that he would assume not less than authority tells us that he would assume not less than authority tells us that he would assume not less than authority tells us that he would assume not less than authority tells us that he would assume not less than authority tells us that he would assume not less than authority tells us that he would assume not less than authority tells us that he would assume not less than authority tells us that he would not a series of the authority pounds.

For our present purpose, we will take 30 pointly per square fort as the mit presents, but because of the long and finely tapering low which represents 5,000 a square fort of the total projected area, we must be careful to make a proper reduction for the first fifty feet of the shift exposed above the variet line. Opinion which is not the reduction which should be made in the only four on the pounds and others would go as high only four on the pounds and others would go as high as eighteen or twenty. We will assume a pressure of to pounds per four, which gives a total endon pressure for the low of 59,000 pounds. Above the bow these same thirty feet of superstructure which presents a practically that surface against the whol, and the presure on this area of 3,000 square feet will add another 90,000 pounds to the load. To this we should add 1,500 square feet, presenting the projected area of the foremast mat the forward sanokestack; and share these present arounded surface to the which, we will reduce the unit presente to 20 pounds, which will add another, 20,000 pounds to the redstatus.

We have now exhausted the 9,000 square feet of area presented normally to the what by the total cross-section of the ship; but in a vessel 900 feet in leastly, the intervening squeets between successalve structures are so great, that we must make a further addition. We shall find that the second and third smokestacks, the mainment, the 80 or more lifeboats, the projecting deck success. The crosses, the standing sear in the way of stays, abroads, etc., will add at least another 4,000 feet.

upon which the wind implages. If we apply the reduced unit pressure of 20 pounds per square for this, another \$8,000 pounds must be added to the sale Finally, we have to consider the skin friction and making, which, if we take account of the thousand portholes, the hundreds of stanchious supporting deck the partial-vacuum effect of the square end of the wide deck structures and of the broad structure and of the broad structure and of the broad structure and the total standard and the structure and the standard standard

In summing up then, we find that there is a estal of 275,000 journals of armospheric resistance, flux be wind and the speed of ship; and a simple calculation shows that to overcome this, at a speed of 18 km/s, would require from 12,000 of 13,000 offsetive known-power, or say ulton 20 per cent of the total effective known-power, or say ulton 20 per cent of the total effective known-power of the ship.

Now here is a subject, which, if our calculations for approximately correct, any well be commended to the consideration, not morely of the builders of large schemliners, but of smaller craft of moderate dimensions, and here, but of smaller craft of moderate dimensions, and no topical boats and destroyers, which are added soon to steam at high speeds against winds of considerable strength.

#### Preventing Corrosion of Iron and Steel

As a part of its investigations relating to encious in mining, the furers of Mines has undertaken to develop a method of preventing the corrosion, by neds water from mines, of from and sixed med in mine equipment. A paper entitled, "An electrical tie method of preventing corrosion of from and select," describes experiment in councetion with an electrical time of the control of the control of the method of preventing corrosion. The results undertaken method of preventing corrosion. The results in the construction of mining equipment, as well as for the protection of structures exposed to the neith waters of stemans.

According to the electrolytic theory of corrosion, the corrosion of Iron is an electrolytic process. The Iron goes into solution no formus ions, and these ferrous ions are collision to formus ions, and these ferrous ions are collision by the conjugate of the water to fee plo, fone and precipitated as feer in the water to real. Simultaneously with the formation of the ferrous ions, hydrogen is liberated to ferrous to the liberation of the formation of ferrous ions and the liberation of hydrogen are accommunited to a transfer of electricity. The electric current flows through the neutral from the point where hydrogen is liberated to the point where from is dissolved, and through the electrolyte from the point where iron is dissolved to the point where hydrogen is liberated.

If, now, a counter electromotive force he imposed, the current may be made to flow in the opposite direction, and the solution of the from may be prevented. This fact has been made use of previously in an electropite method for the protection of holiers manual corrosion. The method consists in submerging a har of zinc in the holier water and connecting the zinc electrically with the holier plates.

In the experiments of the Bureau of Mines, carbon was used as the mode in place of zinc, and the E. M. F. required was furnished by a storage battery.

required was furnished by a storage battery.
Experiments were made on steel plates 1 inch by
2½ inches immersed in sulphurle-acid solutions. Sulfulie arrangements were provided for renewing the need
and for stirring the electrodyte. It was found that the
current density required to protect the plates depends
on the strength of the need solution, the amount of
oxygen gas present in the electrolyte, and the need concentration. The first-manned factor is probably of least
lamportance, especially in dilute solutions.

The rate of flow of electrolyte over the surface of the metal is by far the most important factor

With the lowest rate of stirring used in the experiments—35 recolutions per minute—mid in aid concentrations not greater than 1/100 normal (500 parts per million), a current density of from 0.5 to 0.8 millisusperces per square inch reduced the corroson loss to a nesligible quantity, whereas with the starter rotatling at a speed of 450 revolutions per minute and a current density of 2.0 millimperces per signare inch the corrosion loss automated to 25 per cent of the loss on the unprotected plate.

If was found that the current density required can be calculated from the loss in weight of the metal index the calculated from the loss in the calculated from the loss in weight of the metal index the given conditions when not protected and the electrochemical equivates are rent density and fs. M. F. required to prevent corrowned are given given by the prevent corrowned and the provent consistency of the prevent corrowned are given to the provent consumption per search watte, and the search consistency would be approximately 0.75 for watte, and the electric energy would be 66 kilowett bar per square foot of surface per year. These laborators best were applicanted by tests on a large scale with several account of the constant and for the prevent of the control to the control of the control

#### Engineering

THE PROPERTY OF THE PARTY OF THE

Comments of this British Navy.—The First Lord of the British Administry, reporting on the growth of the British many, resuntly stated that the navy would increase in the mest sightleen months as follows: A torpudo boost destroyer same a week for the next nine months, a lightle-sension every thirty days for the next twelve mostles, sand a super-dreadnought of the latest type overge-dward-stays layer for the next eighteen months.

Completion of Ambrose Channel, New York.—The Arrise anginees Bave reported that the deepening and arrise anginees Bave reported that the deepening and excepting of Ambrose Channel leading into New York Hambor is finished, except for a few minor details, and no 'burther appropriations for construction will be meeded. This great artificial channel is 7 miles lung, 2,000 beet wide and 40 feet deep at mean low tide Ar higher it no be leithlantly lighted by buoys that the largest occass securiers can enter with perfect safety. The work weakepun in 1901.

The New Gladstone Dock at Liverpoot.—The fines Gladstone Dock at Liverpool is 1,020 feet long. 129 feet wide at the entrance, and carries a depth of waker over the sills of 40 feet at high water of ordinary againg tides. This dook is the first installment of a scheme is avolving the exponditure of \$15,000,000 The purposed work includes also an entrance lock over \$70 feet in length and 130 feet in width, and in the madde dook area there is to be a half-tide dook of \$154, acres, two branch dooks each 400 feet wide, with a pier between them over 1,300 feet in length.

A Past in Stone Cattling.—Our contemporary Engineer confine attention to an interesting work of stone certifing commercial with the laying of underground trolleys recently the solid stone Bont Neuf, Paris. It was necessary to cut through the solid stone massonry two trunclets, 4 feet wide and 6 feet deep. This would be an intereminable task fit twee cut by massons in the ordinary way. The work is boung done by an electric motor connected to a drum, from which endless cutting were are carried overhead and around sheaves placed in pits which have been sunk to the depth of the trench to be our

Battle Efficiency of the United States Navy.—Tho shall standing in lattle efficiency of the U. S. Navy shall in the battleship class the "Idaho" is in the lead, while in the totroped class the list is headed by the distroyer "Whippie." Out of a possible 100 points for gather, scored 100 points for gunner, and \$78 for engineering, the final ment mark being \$94.5 This ship is in command of Capt W. I. Howard. In the torpido class, the distroyer "Whippie" stands first, with \$97 for gunnery, \$15 for ongenering, and a final ment mark of \$5.9. Her commanding officer is Lieut. M. K. Matterill.

Tracks Should be Scientifically Designed.—In an admirable paper road by E. B. Milure before a technical security, the writer draws attention to the need for a scientific invastigation of the atrease to which the road-loid of a rulway is subjected. But quotes from an investigation made by O. E. Solly, in which that authority found that after careful consideration of rul-loading, the behaving, depth of ballist, e.e., the structure for a loading of 60,000 pounds per ade should be Thea 7 inches deep, 9 undes wede and \$\frac{1}{2}\$ feet, for single track, ballist, 12 inches of sono and 12 inches of gravel. The rail should be 7 inches high with a 6-inch, base.

The Lostachberg Tunnel In Operation.—The new Lostachberg Tunnel Route through the Alps which was offensily opened on June 20th, is now in operation. The distance from Milian to Paris via the Mont Cenis unture is 560 milies; through the 8th other Albert of the Standard through the Simplon-Lootscherg and Neuerlack it is 513 miles, and through the Simplon-Lootscherg and Neuerlack it is 513 miles. The new line is 43.47 miles in length. The tonnel itself is 9.07 miles long, and it cost about ten million dollars. The line is electrically operated by locomotives of 3.000 horse-power weighing 112 tons, and an overhead system using a current of 15,000 volts employed. The locomotives of 14.0-ton trum up the maximum grade 2.7 per cent at the rate of 30 miles as hour.

Night Mortar Piring.—It is the opinion of the officers that virtuessed the recent night target practice at Fort Hancock, New Jersey, with 12-linch mortars, that if the vessels of any foreign fleet attempted to enter the harbor by night they would be destroyed by the plunging fire from the mortar batteries. The practice was done at a target 12 feet square, which was towed by a tug. The first three and fifth shots hit within a 50-yard radius of the target; the fourth fell a triffe short, and the other five somewhat overshot the mark. Capt. H. S. Kerrick, attached to Fort Hamilton, said that the practice showed the mortars to be the best defense for coast fordination, since mortar firing was now so advanced as to be fully as accurate as that of the heavy, direct-first current.

#### Electricity

Push-button Gas Lighting.—An electric gas valve has recently been invented in Parts which works with direct pressure on a gas outlet. It may not be generally known that only a slight pressure is needed to hold a valve down against the pressure of tho gas. The device constant of a very small flat metal chamber scoresed in between the fixture and the burner, and the gas onters the between the fixture and the burner, alghting as effected high citing gas into a small tube adjacent to the mantle wheth centains a platinum spiral traversed by the current to bring it to reduces, then it is raused to white best by eatlayte action of the gas, producing a fiano to light the mantle. Lighting follows instantly on pressure a button mantle.

Electric Line for Constantinopin—The project for running a metropolitan electric line for Constantinopia is well under way according to recent reports, and the scheme includes the formation of what is known as the Ottoman Metropolitan (Company, capitalized at \$5,000, 000 for the purpose of building and operating the line. The concession for the enterprise has now been awarded to the Deutsche Bank who were the original promoters. From the starting point at Stamboul the line crosses the foliage life and reaches Pancadid and Shahif, running throughout the course in double track. Work is to be finished as far as Pancadid in 123, years from Ottober 1st, 1912, according to the terms of the contract, and the rest will follow within a 10-year period. A new bridge over the Ottober 1st, and the rest also several but the company for a branch line going from Routh to Dolma-Baghteheb, also a line from Stanboul to Venkapin.

Electrifying Paris Suburban Railroads.—M. Mazen, a prominent railroad official, gives some interesting in-furnation on the scheme for applying electric traction on the western suburban railroads in the region of Paris The magnitude of the project will be seen from his state ment that the railroads entering the three depots of St re. Montparnasse and Invalides have rolling stock ounting to 1,500 cars and 200 locomotive likely that the direct current electric system at 650 volts will be adopted, and this will mean the use of about 500 motor cars, together with trailers Sub-stations along the railroad line will furnish current to the third rail, and will receive their supply from three-phase 15,000-volt hines coming from the central stations. That the work is in progress will be noted from the fact that the con tracts for two large power plants have already been awarded. These stations will be located at Moulineaux and Bezons, upon the Seine, and when completed they and pooning upon the term, and won complete they are to furnish upward of 100,000 horse-power, using steam turbine groups of 7,000 horse-power size. At a future date it is likely that the Rhone and Geneva will be called upon to furnish a large amount of current for Paris over a power line, and on the other hand there is a likelihood a power line, and on the other hand there is a likelihood that the Lens coal lunes in the north of France will also be called upon, using a 100-inite power line. A type of third rail will be used having collecting shoes rubbing over, being mounted upon blocks of treated wood. The sub-stations will have from 1,000 to 2,000 horse-power rotary-converter sets which need no transformer, but will give a direct change of high-tension alternating cur reut into continuous current at low voltage,

The St. Denis Steam-turbine Plant, -In view of the derable additions which th e great St Doms ste turbine plant has received of late, it will be timely to turnine plant has received of late, it will be timely to give a rezumé showing the leading features of the station as at present installed. It will be remembered that the plant lies not far from Paris and is one of the sources of the city supply both for light and traction, including the extensive subway system. At present the station has five Brown-Boveri steam-turbine alternators of 4,000 kilowatts, four groups of 6,000 and one large one re-cently installed of 15,000-kilowatt (20,000 horse-power) capacity. These turbines work at 750 revolutions per minute and the alternators deliver 10,250 volts. groups serve to produce three-phase current, and the plant has also four 6.000-kilowatt groups used for twose current supply and running at 835 revolutions per Two other turbine alternator sets are designed to produce either two-phase or three-phase current and use one turbue mounted with two different alternators the same shaft Condensation for the ton gr taken care of by ten surface condensers in the br ment, each one using an air pump driven by a direct-cur-rent 50 horse-power motor, while the large 15,000 kilo-watt group has a condenser provided with a 60 horsemotor for the air pump and a 250 horse-power ation water pump There are also four "polymoreirculation water pump There are also four "polymorphie" dynamo groups, each one composed of two alternators (two-phase and three-phase) coupled to two 550 voil direct-current dynamos. Any of the machines can serve as a motor for driving the rest so as to have various suppless of current. For the direct current, the plant uses a small turbine set and also two large motor-genera-tors of 1,200 kilowatt size and two of 600 kilowatts, work-

#### Science

Moving Pictures in Greek Schools.—A consular report states that the Minister of Education at Athens has opened negotiations for an early matablation of no fewer than 4,000 natural color moving-picture machines, with supplies of films, for use in the State schools

A New Method of Determining the Dev-point is described by Higgounderfi in the Physicalizethe Zatischriff as follows: Take n vessel of some metal that is a good conductor of back, n g, n silver on copper one. Pill it with water, and introduce the bulb of n thermometer. Then add slowly some sait, such as sal ammoniae or hyposulphite of soda, the solution of which lowers the emperature of the mixture, meanwhile strange the liquid with the thermometer. At the precise moment when the until of the production of the development of the strange casted with mosture note the temperature of the strange of the strange of the development of the strangending of the development of the strangending of the strangen

Radium Emanation Therapy was discussed by Dr Saubermann, of Berlin, in a recent before the Bongen Scoreju in London. As reported in the London Times, the becturer stated that in the whole range of discusses of metabolism, mediading goat; remarkable or multiple and a second control of the remarkable of results had been obtained by the use of water artificially charged with radium emanation to a much higher degree than the water found in any natural spring. As to the claims put forth all over the continent by various spass, he said that in the majority of cases the amount of radium emanation in the water or the air was too small to have any physiological effect.

Alt Carrents at a Height of FHy Miles above the scart are discussed by J Islamin Clark in the Quantity Journal of the Royal Networkopeal Sweety, on the base of observations undea timan places in southern England and northern France of the drill of a particularly length and persistent meteor train seen on the inglit of February 22nd, 1909. Mr. Clark lumself size the train for 10 minutes. The most remarkable conclusions drawn by the writer relate to the velocits of the upper winds at Aurious levels, as indicated by the movement of the train. Thus it appears that between  $190_2$  and 51 mHz sultrain the strenk lay in west vanied of ever 170 mHz in hour, while at 511  $\gamma$  mHz with the current was almost from the each with a velocity approaching 200 mHz as a hour. Those conclusions hardly agree with the prevailing conception of the stracklay ever as a region of gentle winds.

Hall Insurance in Great Britain is fairly general in Half Insurance in Great Britain is fairly general in only two counties, viz., Bedfordship and Huntingdon-shire, where its providence is explained especially by the fact that these counties were visited by a very destructive harlstorm in August, 1906. The two counties just mentioned and parts of Cambaidgeshire and Northamptonshire are subject to rather frequent hadstorms, but over the greater part of the British Isles loss from had is so small as to be almost negligible from the standpoint of the underwriter. The British Board of Agriculture which has been collecting information concerning had insurance as enried on by British companies, has received prospectuses from six of these concerns, five of them charge a uniform promium per acre for the whole country, while the sixth follows the more equitable plan of varying the premiums according to the meteorological history of each section, i.e., the number of damaging hallstorms that have occurred within a ten-year period The results of the Board's inquiries, together with a chart prepared by the Meteorological Office showing the num-ber of days had has been reported during July and August at different places in the United Kingdom ten years 1903-1912, are published in the Journal of the Board of Agriculture for March, 1913

Recovery of Metals From Smelter Gases -- By means of Cottrell's method of electric precipitation appreciable amounts of precious metals have been recovered from smelter shine gases, which have been heretofore con-adered as waste products. At a prominent New Jersey copper smelting works a plant to treat gases arising from elting slimes is already about completed and several smelting companies are preparing to install converters. The copper as recovered from the ore and as received at the electrolytic refinery, usually contains a conand raise amount of silver, gold and other precions modals. During the electrolytic process most of these elements settle out from the electrolytic. This sediment or mixture, colled sline, is then treated in another department for the recovery of the presums metals This is usually done by drying the shine and driving This is usually done by drying the shine and drying off the volathe elements by means of a furnice treat-ment. Some of the silver is volatilized and even small quantities of gold. The heavier metals condense in the flue according to their relative weights Gold is found to the flue dust near the exit from the furnace while silver, being lighter, is carried further along wine siver, being lighter, is current terriner among At points further removed are found antimony, arssine, selentian and other elements. The presence of zinc, arssuic and antimony seems to have an appreciable effect on the deposit of silver and samples of dust from such refineres have shown the amount of silver to range from 100 to nearly 2,000 ounces per ton.

#### Cooling Gas Engines in a New Way

I N most gas construes, host be removed by circulating and the exhaust valve. About thirty per cent of the heating value of the fuel thus passes into the metal of the engine. Beadles, external water cooling is the cause of many disadvantages under which the gas engine labors and which that its star. There are also secondary effects. In order, for example, that the heat may then from the fune surface of the metal, where it enters, to the unter surface, where it is been except the most officer of the metal, where it enters, to the unter surface, where it is been except that the surface most function of the metal where the enters of the metal surface, where it is been except that the third of the enters of the metal surface is the enters of the enters

To overcome those difficulties Prof. Bertrum Hopkinson of the University of Cumbridge proposed, in a paper recently read before the Institution of Mechanical Engineers, to apply the cooling medium inside instead of outside the eithider.

The idea of introducing water into an internal combustlon engine is not new, as Prof Hopkinson admits. but it has never been effectively carried out because the conditions which must be satisfied if the injected water is to act as an effective cooling agent have no realized. Of these conditions the most important Is that the water must be projected in comparatively course drops or jets, directly against the surfaces to be cooled, so that it reaches these surfaces in figuid form without much loss by evaporation. Furthermore, it must be distributed properly, so that each portion of the metal receives water in the proportion in which If the water be turned into stemu It receives hent before reaching the metal, it would exert fittle if any cooling effect. If the water is not properly distributed, those portions of the cylinder walls and piston which do not receive an adequate supply must be conduction to the properly cooled portion the heat which they receive, and, in consequence of the hespalities of temperature thus set up, an important advantage of Prof. Hopkinson's method of cooling (substantially nulform (emperature) is lost

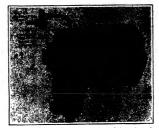

While the spans have in the past proved useful for the prevention of predigition and for the softening of the explosion, they are not effective for cooling. Prof. in Hopkinson's method of lateral injection is clearly revealed in the numeral illustration. Cold water is to jected through a hollow consting which projects into the disperted through a hollow consting which projects into the oncombostion chamber and while its proceded with a numter of holes or small nozice alone 1/22 of an inch in diameter. The Jets thus, formed are comparatively course. Even whom projected into the finance, the water performs lits function with but little evaporation on the way. The Jets are directed to all parts of the sorface of the combostion chamber and against the face of the below.

But what about curro-don? By the shuple device of regulating the amount of water injected in such a way that the temperature of the whole engine is maintained well above 100 deg Cent, this apparently insuperable difficult has been coverous. Every drop of injected water is builed when it renches the walls, and no liquid can accumulate to form sulphure acid with the sulphur dioxide contribed in most producer-gas. What little gas the large drops of water abose h is at once driven off when they strike the hot metal, because the water is almost instantly converted thou steam.

It be sufficient to toject water on to the surface of the combustion channels and the head of the poston only, the whole of the coding of the harrel being effected by conduction into the ploton which is best kept cod by the projection of water cuto the head when it is men the in-center. This, of course, be the opposite of what occurs to a juckeded courie, in which the heat those from the piston into the jacketed barrel. By taking advantage of this fact, the application of water is confined to places where it can do no harm, nous fulling out the shifting surfaces. This is a point of some importance if the water contains much dissalved and

In his paper Prof. Hopkinson gives an account of some toets made with a 50 horse-power Crossive engine, raried at 40 brake forse-power, 11% inches the diameter by 21 horles stroke, having a speed of 190 revolutions per minute. Out) the external water-cooling system was removed. The oughts was run continuously far 22 hours on no electrical band with cost gas 11 developed during this period 43 brake horse power out the average, and the average mean effective pressure was 101 pounds jet square lack. When lacket dotted the engine would not develop amore than 49 brake horse power confinemently without corrhesting, and mixtures giving a mean pressure of more than 100

pounds per square inch produced excessive maximum. pressures (over 500 pounds) with violent thumping explosions. Water injection reduced the assumum pressure by over 100 pounds per square inch and made the explosions almost insudible. The formation of the steam involved practically no thermodynamic loss. The

Prof. Hopkinson's method of internal injection of water to cool gas engines.

quantity of water used averaged 102 pounds per hour. The temperature of the engine varied from 150 dec, to 180 dec, feel No water was visible on the platon or the spindless of the vaives. When the engine was picketed und gave the same power for short periods, the Jacket water removed about 67,000 British thermal units per hour, which would be sufficient to evaporate 108 pounds of water at a temperature of 20 deg. Centmoder atmospheric pressure. Watereve difference there may fave been between available heat and amount of water value and the superature of 20 deg. Centmay fave been between available heat and amount of water evaporated is accounted for partly by greater radiation loss, and partly by the reduction in fiame temperature produced by the steady.

perature produced by the steam.

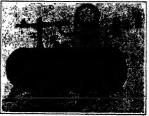

The engthe consumed 15 feel of coal gas per brake horse-power hour reckoned at almosphoric temperature and pressure. This is approximately the same as it burst when developing the same power for short periods when jackets.

When coupled with a dynamo in a factory engine room, with an increase in speed from 180 to 105 rerointions per minute, the engine developed for several weeks in times 50 mike horse-power with coal gas for several hours together—an increase of 25 per cent on the maximum continuous load which it could safety carry when Jacketed. Since then the engine has been in regular service for two years with an antiractic suction producer. A syst there has been no trace of corroston in the engine, although some corrosion has been observed at the heads of the exhaust pipes where the guess implage on the metal. This corrosion can be avoided by engine that are removed the artists.

a volded by suitably arranging the pipe. From the nature of this method of coulting, it would seem attract or that method of coulting, it would be income at the country of the size of the engine. The method has been applied to an engine of 18½ inches hore, giving 1036 bines power Oechel hanner engine of 30 inches hore. The trials of this larger engine proved beyond any question that the largest cylinders now built can be couled entirely by water highest on and that the quantity of water used—about 24 pounds per brake horse-power hour—seems admost hiderendent of the size of the engine.

#### A Stationary Chemical Engine

THE value of carbonic acid gas as a fire extinguishing agent has long leven recognized Statistics show that from hirty to eighty per cent of all fires (in the different cities where the figures were gathered) are extinguished by chemical curines. These fagures, or course, relate to those entires which are portable either by hand or on wheels. The latest type of chemical endine is a large stationary outfit intended for use in

he new chemical engine with section of cylindcut away to show working parts.

office buildings, private lowers and buildings, private lowers and buildings of the signal signature was installed as a New You last week and demonstrated for representations of the signal several insurance see and city officials. The accompanying illustration clears:

The accompanying illustration constraints working parts of the english. The steel was very contrainted to the english. The steel was throughout with lead and is teered to english a surported below its center on an english steel in the I. is supported below its center on an english steel in the steel in

At the top the tank is connected with a characteristic pipe D which may be coupled with any namine of with may permit the heads A, in the hand value B with home A, distributed throughout the building. From the characteristic hand with the cylinder B projects a small pipe which assume in a small gold plate G, through which a subsule with a driven. At the top of the tank is a handsale consideration of the connection of the control of the connection of the connection of the connection of the connection for carrying a safety value B and an overslow value B.

To charge the outline the piston rool is moved a blood to the left, allowing the frame K with the besides Leib is removed through the handbole. With the considerable to the removed through the handbole. With the considerable valve. This allows a certain quantity of vator to he placed in the tank each time it is filled. For a tank holding 100 gallons of water shout fifty pounds with the product of the considerable with the pounds with the pounds of the considerable with about sixteen pounds of sulphurds acid, after which the cap J is replaced and firmly screwed down.

It will now be seen that the air space in the english and that in the julpe system are separated by the water line which fills the cylinder K nearly to the top, and by the small good displayang d perforated with a milante hole. There is, therefore, no communication between the two bodies of air except through the cylinder, which is normally shut of by the pitton, and the displaying d. By means of any suitable air pump the air is compressed in the pipe line to about ten pounds pressure. This is accomplished by attaching the jump to the lift by the lift of the fault through the small displaying d, and when pumping ceases the pressure is equal in the tank and the pipe line.

line may be in fire, the heart of which automatically opens one of the sprinkler heads, or in case a hardwise is opened, the present is lowered in the pipe-line at a much finite rate than in the tank, as a result of which a pressure is induced against the photon in the vibility of the pipe-line at a much finite rate than in the stark, as a result of which a pressure is induced against the photon in the vibility of the pipe line. The subject is immediately uplied into the sold solution and the resultant each of the solution of 125 to 150 pounds per square inch. This forces the water up through the pipe H. through the or the pipe H. through the order of 125 to 150 pounds per square inch. This forces the water up through the pipe H. through the vibility for a first in case of far. The busser may also be likely to fail in case of far. The busser may also be set to sound a large gong O if the pressure should redset to sound a large gong O if the pressure should redset to sound a large gong O if the pressure should redset to sound a large gong O if the pressure should redset to sound a large gong O if the pressure should redset to sound a large gong O if the pressure should red-

be connected with a requiar fire alarm system.

In the demonstration mentioned the tank was placed
on the top hoor of a six-story building and connected
with a system of aprinkler heeds and hand valves, in
the basement. From the time the water was turned
on at one of these laqued valves until it reached the outtie of the hose, a period of only six seconds elapsed.

#### The Area of Canada

I N an article on mapping the world, published in the Schusturic Aurancan of Joly 20th, we stated that the distortion produced by the Mercator projection gives one "the notion that Chanda is twice the size of Canada is less than that of the United States." As a matter of fact the area of Canada is less than that of the United States. "When who when the state of Canada is less than that of the United States. "When the state of Canada is less than that of the United States. Canada is a 3,729,805 square miles as against 3,009,739 of confinential United States stylicot Alaska.

An Interurban Airabia idate.—It is stated that passage ger airabip service is to be astablished in Raginard by: a company which will be expitabled at \$1.250 CM. The sixthips are to fravel from Lordon to Religibles, Main charter, Birmingham, and Parke, some other phone.

# Pedagogical Laboratories

Children are Studied in a Russian Laboratory from Their Birth Until Their Twenty-first Year

By Dr. P. R. Radosavljevich, New York University

L'Espaido importe cell deny that an L'Espaido importe de principologico de l'Espaido importe de l'America de l'

reseats basis we need: (1) Peda-regical schoratorics, which ought to be the real sancts of all true educators would know the pedagogical truth understand the real workings of normal mind of school children and the nature and the postulates of school educational reforms; (2) Pedagogical elimins, the function of which should be to ever and cause to be remedied, as far wibie, physical defects and comsicable diseases that might interfere with efficient school work of pupils; (8) Experimental schools, the purpose of which is (\*) to find out by experiment schether, how, and schere the school educational ems may be worked out, and (b) to save time, money, and energy of other people in performing similar elaborate experiments which, of course, require most favorable conditions, especially unhamp ered work with all the needed resour at hand, in order that results may be reached, both freely and securely, and not by mere subjective discussion and one ed theoriging

We have no real, scientific experimental we hoole and pedagogical ciluies. The few attempts made in this direction were quast-scientific undertakings of private individuals (Dewey, Rieddie, Lietz, Fey, Tolstoy, Yenzel, Ferrero, Montessori, etc.), who were willing to reform the present who were willing to reform the present school education, but had no incessary means for such a bit tank. We have only a few pedagogical periodicals, series of monographs, associations, societies, clubs, congresses, institutes and academic lectures. Germany leads in this field. She has about thirty scientific pedagogical periodicals dealing with the problems of experimental pedagogy, about ten different series of scientific pedagogical pediadogical medical pedagogy, about ten different series of scientific pedagogical metals of experimental pedagogy, about ten different series of scientific pedagogical metals of scientific pedagogical metals of scientific pedagogical metals of scientific pedagogical monographs, acceptance of scientific pedagogical metals of sci

A corner in the Zürich laboratory abowing models used in teaching anatomy and physiology of child's central and sensory nervous system.

Apparatus of Zürich isboratory for studying pupil's association and reaction.

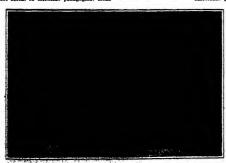

Apparatus of Zürich laboratory for studying pupil's memory, perception, emetional phenomena, etc.

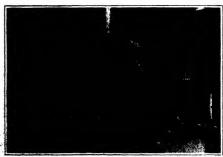

graphs, about 30 associations for the study of school children, etc. Next 16 Germany comes. Swiftzerland, then Beiglum, Holland, France, Russla, Italy, Sweden, Austro-Hungary. The majority of Germans and other European and American psycludegical Inditutions are more or less engaged in some pedagogical investigations with special reference to the psychological bads of 11.

The first inhoratory which devoted its energy to real pedagogical experiments is Meumann's Laboratory in Zarich Men-munn's residence in Zürich (1807 to 1905) signified the birth of experimenlin laboratory tal pedagogy. His laboratory soon be-came the main station of scientific pellagogical research, a Mecca for many foreign students who wanted to get pedagosleni facts and were willing to labor in order to observe the real educational conditions. Later he founded similar laboutories in Konlgsberg (1996), Münster (1907). Halle (1909) and Lelozig (1910) In Unmburg he has his latest laboratory, and in that city he is organizing the first International Institute for the Study of School Children - It is a hopeful dux for education that a man like Prof. Memanan, buoself a master in experi mental psychology and philosophy, turned to the practical problems of pupil's de velopment and school instruction combines in a very luppy and musual was the different analifications of a good observer of children and pupils. He has the very first conditions for success (1) a loving interest and the clem sympu-thetic hesight which grows out of this, and (2) he never allows his sentiment to get the better of him, looking at the child from an importful and publised technique cal point of view His laboratories were, therefore, always filled with caracst stu His laboratories were, dents of all nationalities (Messmer, Ebert Mugneff, Zoneff, Smith, Pentschew, Winteler, Ziegler, Engelsperger, Abrancoff, Mayer, Schmilt, Pfelffer, Eckhatelt, Kar-Alblon, Goddard, Starbuck, rust, Borst-Durr, Keichner, renberg. Hoesch Ernst, Borst-Durr. Segal, Gineff, Rakitsch, Chubrovich, etc.), and his lectures were attended by as many as one thousand students

Memanias Informaties and Institutes (1) collect anthropometric and psychophysical data for the purpose of establishing norms and for necertaining such relationships as may be of service to school editention. (2) apply precise psychological apparatus and thartmanets, and accurate scientific methods to scientific school editentional problems, particularly methods of hydror teaching and comony and technique of learning, (3) examine school editerior fellenting, (3) examine school editerior follenting, (3) examine school editerior fellenting, (3) examine

Apparatus of Effrich laboratory for studying child's reading and visual

educational management, and (4) give practical and theoretical instruction in experimental ped Pedagogleni investigations are carried out also in

mnoy psychological laboratories and institutes.

Another type of pedagogical laboratory is remarkable and is the first of its klud in the world. It is the Psycho-Pedalogical Institute in St. Petersburg. This Psychological Institute in St. Petersurg, This institute was founded in 1006, by the generous gift of a great Russian judianthropist (V. T. Simin), who gave to the institute in beautiful "internat for the Study of Mini as a Subject of Education," and also 52,000 rubles. The director of this institution is the fumous Russian biologist, V. M. Bechtereff, president of the Psycho-Neurological Institute topened on February 1908), founder of the first Criminological of Russia (St. Petersburg, 1908), and one of the greatst scientists in Russia. The plan of the psycho gical institution is to provide for 10 to 15 beds to study the mentulity of buman beings as subjects of educa-tion. Each subject is studied and educated from birth up to 21 years of uge. The first child who entered this institute was a baby boy, named Seryoja Parlnkin, who is noder constant care and observation of two physicians (Drs. K E Lityshelden and T P Spirtoff), and three unrses

The programme of the studies of these babies is too long to present here. We may mention, however, that it includes not only the problems of the present, but also those of the past of the child, i. e., his hereditary traits and his preparal life. Here they study carefully the child's organism with all its function, and the dependence of the organs upon environment. The child's temperature is noted every day as well as its pulse its breathing, and its nourishment. From time to time the child's weight, tody proportions, leelhing and various discomforts (injuries, sickness, etc.) are recorded The whole development of the sense organ is studied. All these observations will give the mos precious practical conclusions in regard to the first days of a child's psycho-physical life, the first steps of his bodily growth, which is closely connected with the in addition to that a series of interesting scientific and practical questions are studied viz, habit formation in children, antural (native) and artificial (due to exercise only) movements, the child's relation to conscious and unconscious objects, his relation to his new acquaintances and friends, his fears,

Such un objective, patient and constant individual study will be of immense value to pedagogy, physiology and psychology of the child. The 81 Petersburg instituiion should be a great aid toward making good pupils and good teachers. Logically, it does seem that we m know by experiment, before we can teach, or before we can show others how to leach school children. Curi onsty enough, we have thousands of normal schools but are just beginning to talk about the need of the kind of school that should precede the normal school Sittl we ought to be content that the old school method. founded upon a rigid faith in the book and traditions processes, is loosing its ground almost duity.

#### The Other Side of War

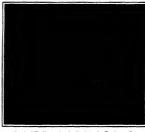

RY this caption Dr E Helme, writing in Le Temps, means to indicate the rougher side with which the individuals come into painful contact who feel within their own skins the effects of modern weapons their own same the question Will war be more muruerous the question will war be more muruerous that capt answers with an unhestathing affirmative. Wars, it is true, instead of hasting a hungrian towars, as in bygone days, now hast only a few months. But this, he says, simply means that the blows are heavier, and the combatants are sooner exhausted. The Russo-Japanese war lasted ouly eighteen months but the battle of Shu Ho, in Mancharia, justed tweive days. Thus, although the number of killed and wounded per day in the actual fighting of the Franco-German war not have been greater, the losses in buttle in the Manchurlan camonize were much greater to the aggregate. The truly terrible fact, however, is the increasing proportion of mortal to non-mortal wounds. In the Franco-German war of 1870-71, the victorious army lost ten men killed to every 58 wounded. In 1904-05 there were ten Japse killed to every 37 wounded.

Coming to the explanation of these facts, Dr. Helme dismisses as "o troublesome legend" the story that ern bullets, being smaller and moving more rapidly, inflict less serious wounds Really slight wounds, he heal more quickly and more thoroughly maintains nowadays than formerly; but the severe wounds are no less severe and much more frequent. To litustrate this the writer considers, first, the form and structure lins the writer considers, first, the form and structure of projectities and then their motions. The lance coeff handled inflicts severe abdombial wounds," and the Japanese cut-and-thrust bayonet "ly terrible," but the writer's main theme is the effect of projectiles

First comes the rifle builet, "but yesterday the Que forderess of Battles." The German builet consists a core of lead hardened with antimony, covered with

a steel jacket. It is none the less efficacious because s off and acts on its own account the jacket often com as a lagged fragment of metal, lacerating the human body. The French bullet, though not jacketed, is not kinder to the enemy. It is longer and sharper-pointed than the German, and is made of a mixture of copper and sine. Becoming bent by ricochetting, it someti and zinc. Becoming bent by riconerting, it sometimes enters its victim's body in the shape of a hook; some-times it "tumbles" in its flight, enters broadside-on, and makes a long, gaping wound. Up to a range of 800 meters these rival horrors are one as bad as the

The gravity of the wounds depends on a multitude of conditions. On the rocks of San Juan, where the bul-iets ricochetted in wonderful fashion, the American cons reported frightful injuries. It was the same

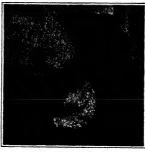

Prof. Wladimir Michailovich de Bechtereff

He was born in 1857 in Wiatka (Russia) and is on he greatest living Russian scientists, whose works are shed in Russian, German, French, and Bohemian

at Spion Kop, in the Trausvaul. It used to be said. optimistically, that a bullet heated by friction in the barrel of like rifle would reach its object asepticized by friction; but this hope has been dispelled by the re-searches of von Koler, showing that the temperature of the projectile never comes within many degrees of that is necessary for the destruction of micro The crueity of the modern bullet has been anginented, too, with the increase of its rotation, so that it acts not only as a club, striking a heavy blow, and a perforating point, but also us a gimlet which lacerales the

But bullets, after all, are mild agents of destruction when compared with up-to-date shells. The shell wounds in the war of 1870 were only 91 per thousand; ilie Manchurian campaign th sand; in the Balkan war of 1912 they were four times

Some anthropological instruments which are used in a pedagogical laboratory.

as numerous as in 1870. The shrapnel shell has the advantage (to its employer) of scattering destruction by means of some hundreds of small round bullets as well as the fragments of the shell itself. This "devil's watering-pot," as the Russian soldiers called it works within a radius of 10 to 30 meters; at 100 meters its "dewdrops" are still lively enough to penetrate 6 centimeters of pine board; at 200 meters a turban will protect the head from their effects. The tortnone incisions made by shrappiel are particularly difficult to disinfect. But in spite of all this, and though the ear of the most harder ned veteran is said never to become accusement to the destin-song of shrappel overhead, the common shell is resily more terrible. Its frag-ments, brought to a very high temperature by the ex-plosion, "burn the flesh so as to sompel crise of agony which only morphine can swiet.". shells of the naval guns "not only or asphyxiate, amputate portions of the

Dr. Helme's study of the moves and its effects at various ranges, a sues, should be minutely intere the pomp and circum effects on bones, in particular, are explosive; (2) comminutive; (3) co explosive; (2) comp iting when the range is not gree splinters the bone so thoroughly as quent accusations of using explosive become a feature of modern war no proper to the sone of from 500 to 1, tinguished by the danger of brings ments of soiled clothing, carrying effects are observed only in the main in the spongy extremities there is except when the extravasation of bla d condition of the joint.

The effects of projectiles on soft the ning liquids has led students of some highly interesting experiments. an empty metal vessel makes a small hole to and leaving. But a bullet fired at the vessel filled with water, while it enters the centimeters wide. This very fairly ille cts of a bullet upon, say, a human ste explanation advanced by the experimenter is: ssage, the bullet carries with it molecule of very small mass, but move with great rea being projected in all directions, have & of compressing the lucrt molecules (of the sa medium) and an outburst of the wail of the variefollows at the excess of the projectile." And so it is iliai bullei wounds in the stomach, biadder, the that pullet wounds in the womach, plander, were testines and head, received at short range, profile veritable explosions of these parts.

The writer concludes his discussion with the con-

solution, such as it is, that science and humanity appear in a much better light when we consider that achievements for the benefit of the good men who are

#### A New Wright Hydro-aeroplane

A NEW type of Wright hydro-aeropiane has been de-signed by Wilbur Wright. In the tests which have conducted on the Miami River, near Dayton, O. Mr. Wright has already made more than a hundred successful flights. This new machine, which is known as the Wright Model CH, is remarkable for the ease with which it starts and alighia. The planes, rudder, motor and drive follow the standard Model C lines. The span is 38 feet, chord 6 feet and the surface area about 440 square feet. The weight empty is 1,160 pounds, including the main float, which alon The hydroplane unit consists of a single 240 pounds The hydroplane unit consists of a single fout 6 feet wide, 10 feet ong and 10 inches deep, be-slides a small pontoon which supports the tail. The machine is equipped with a new Wright siz-cylinder, 00 horse-power motor, which drives two Nig-foot propellers

#### One Starter in the English Coast Flight

THE London Daily Mail's \$25,000 contest for the circuit of the British coast with an all British hydro-aeroplane, was started on August 16th from Southampton with phly one participant, Harry G. Hawker, the winner of the Michellu prize in 1912. Hawker carried a passenger, and made his first landing at Ramsgate, a distance of 144 miles from the starting point, which was covered in 143 minutes. His machine is a hiphane equipped with a 100 horse-power motor and with a tractor propeller. The only other entrant remaining on the list of contestants is Frank McCle who did not reach the starting point in time to begin the flight with Hawker, but who was expected to en the contest later in the week.

#### The Retirement of Commissioner Moore

DWARD B. MOORE, retired from the Patent Office u August 15th, after a service as assistant ou missioner and commissioner extending over twelve years, and following service on the examining corp of alout eighten years. Mr. Moore has embered upon the practice of patent law, becoming a member of the firm of Moore & Clark with offices in Washington, D. C., and New York city.

A Judicial Decision Involving the Camera Film

A DECISION was recently hauded down by Judge Hasse of the United States District Court for the Western District of New York, in the case of the Goodwin Film and Camera Company vs. the Eastman Koffak Company, a decision, which, if sustained on appeal, will be of far-reseating effect.

Roth-holders for films were suggested at a compararelyst party period. Their use, however, was restricted. There was a demand for a fischile and rollable film support which could be conveniently carried by the photographer in piace of glass. In 1985 such a film was derised and made practicable by Mr. George Eastman. This film was of paper coated with a golatine brounds which became the negative and which was readily removable from the paper. But there was still a desire for more satisfactory film supports. The paper stripping films were objectionable on account of the not infrequent appearance of the grain of the paper in the picture and on account of the thinness of the film, which made it difficult to handle in the printing operation. In spite of the success striated by the paper film, they were soon displaced by a transparent dexilienitro-cellulose film support upon which the sensitive enulsion was fowed. This film was placed upon the market by the Eastman Company, but Handhald Goodwin claimed that he was its original inventor.

Goodwin took out a patent in 1898 for a photographic and process of producing it which by the Goodwin Flim and Camera Company, and which was made the basis of the patent infringement proceed-ing decided in favor of the complainant by Judge Hazel. In his patent, Goodwin states that a solution of nitro cellulose (not the commercial compound known as celluloid dissolved in airohol or ether) dissolved in nitro benzol or other non-hydrous and non-hygroscopic sol vents, such as may be employed in producing celluloid ns distinguished from collodion and diluted or other hydrons and hydroscopic diluent, is flowed over A smooth, transparent, impermeable film, cap able of being subjected to photographic fluids without being affected thereby is obtained. The sointion ob-tained by dissolving the nitro-cellulose in this non-hygroscopic solvent, is diluted with sleahol or some other diluent, which, like sleahol, serves to dilute or expand the volume of the dissolved nitro-cellulose and increase its fluidity, and which may be and ordinarily is hygrostone, miscible with water and highly volatile. diluted solution is then applied to a smooth and hard surface, from which it may be stripped when dry

Secuse of the high wolatility of certain elements cuntained in the solvents, they evaporated rapidly, leaving the pellicle more or less fluid, until the high beliar elements, which oraporates more slowly were also responsed, where upon it became hard, transparent, and soo-porous, and being without oil or greatines, resident the indirious effects of the photographic emission. The desired result was achieved principally through the high boiling quality of the solvents and that non-hydrous and non-hydrouset in the Tenet Office. These was considerable argument in the Facent Office,

There was considerable argument in the Patent Office, after Goodwits application for patent was filed, in an effort to persuade the primary examiner that a patent for process and product should be granted. The application was finally rejected in 1888. An appeal was taken to the Board of Examiners in Chief, and the diction of the Board of Faraminers in Chief, and the diction of the Board after over the sensing of the patent. The Board in the patent of the sensing of the patent of the Board in the sensing of the patent of the Board in the sensing of the patent of the sensing of the patent of the sensing of the sensing of the sensing of the patent of the patent

Long before Goodwin's day chemists were aware of the fact that chirch-bens old anyl acetate topesessed non-hydrous and non-hydrous properties, and classed them as solvents of nitro-cellulose, gnn cotton and pyroxchene. Goodwin, however, drew a sharp distinction between his solution and the solutions of collection or cellulaid, which was composed of intro-cellulose and complot or distinctly dissolved of efter or alcohol, and expressly disclassed the latter, all the while elatimity and intro-cellulose and an improvement in the specific combination of intro-cellulose dissolved in nitro-bensal or other non-hydrous or membry prospects solvents, and diluted in alcohol or its equivalent. In its decision the court adopts Goodwin's contention.

During the prosecution of the case in the Patent Office, Goodwin became involved in an interference with Reichenlanch. Reichenbach, who had no knowledge at the time of his invention of Goodwin's application, described life process as depocifing or spreading a third southern of interference outline on full recordulose and campion goan is suitable surface. He disclaimed the issue of the interference and canceled his process has been also substant of interference and canceled his broad claims. Subsequently letters patent were granted to Reichenbach, covering his specific process, ansaety a solution of intro-cellulose and campion in methyl or wood alcohol with a quantity of fracel oil and amyl nestate added. Goodwin had never exemblance of his solution to celluloid, which contains campion, the examiner decided that interference with new beautiful to the contains campion, the examiner decided that interference with his switchess of the contains campion, the examiner decided that interference with his switchess of the contains campion, the examiner decided that interference with the Reichenbach was proper. Precuming that his invadication had been allowed, Goodwin practically conceived the results of the contains of t

Meanwhile, however, the Eastman Company ide in accordance with the R keted film supports in enbuch process, and these supports were regarded as solving the problem and were used hirgely in place of The court held that "in departing from the sie elfic formula of its own patent, the defendent util the equivalent of the method specified by Goodwin in this patent and achieved the same result. The Reichenbach solution was concededly grepared with approximately 60 per cent of camphor, which, according to the decreased from time to tim per cent relative to about 22 per cent of altro-cellulose s decrease in the quantity of camphor sufficient to over come objections These objections were the cocking come onjections and pinckering of flus made in accordance with Reichenbach's processa. The court decided that the two processes "are not distinguishable in principle". The improvement in the flus support is due to the combinaof equivalent high and low bollers, and therefore departure in its production is merely within the score of the claims."

if the Kastman Company should lose this case on appeal, the present awners of the Goodwin patent may find themselves entitled to collect damages involving millions of dollars.

#### What Are the Ten Greatest Inventions of Our Time, and Why?

A Prize Article Contest Open to All Scientific American Readers

T 415 November Magasine Number of the Scienciary Amazaca is to be devoted in part to a review of the great inventions of our time. Because a inrea inmediate of Scienciary includes a reason of inventions, it seems to the Editors that their judgment of the inventions produced in our time which descrive to be called the greatest, their appreciant of the relative importance of the paramount technical achievements of our day, would be of pseudiar value and interest. Therefore, it has been decided to leave the entire subject to them

The publishers of the SCHENTIFIO AMERICAN offer three prizes of \$150, \$100 and \$50, respectively, for the three best articles on the topic, "What Are the Ten Greatest Inventions of Our Time, and Why?"

Contestants for the prize must observe the following

- 1. Each article must discuss and answer the follow-
- a. What, in your estimation, are the ten greatest inventions produced within the last twenty-five years? b. What are your reasons for this selection? Justify
- your selection in each case.
  c. To what person or persons is the greatest credit due in the developing and perfecting of each invention which you have selected?
- 2. The entire subject must be covered in a typewritten article not exceeding 2,500 words in length,

and must be treated as simply, lucidly and non-technically as possible.

- 3. In deciding what are the ten greatest inventions of our fine, the contestants are limited to machines, devices and discoveries commercially introduced in the last twenty-five years.
- 4 Since the Neuritric American is "the weekly journal of practical information," and its readers practical business men and inventors, the articles simulited should deal only with patentable inventions and discoveries.
- In order to guide the contestant in deciding what is a great pioneer invention of our time, it is sug that practical success and general usefulness to mult-A modern discovery been suggested long ago and its underlying theory even worked out mathematically, as in the case of wireless telegraphy, but nevertheless it falls within "our time," if it has been made generally accessible and asoful within the last twenty-five years. But commercial within the last twenty-five years. But o The flyas not yet added millions to the na tional wealth; but, for all that, it is a great invention of our time. Mere improvements on well-known and successful devices are not to be numbered among the great inventions of our time Because an invention was first patented more than twenty-five years ago it is not necessarily debarred. The date of commercial introduction not the date of the patent governs invention, moreover, need not have been netually patented, but its subject matter must be of a patentiable nature. Patentability is merely a test of commercial
- 6 Contestants must not disclose their identity. Each article must be signed with an assumed mane and must be accompated with a seated envelope, on which the assumed name is written, and in which the real name and address of the author is contained.
- 7 Contestants must address their articles, accompanied by the envelopes containing their real manes, to "The Invention Contest Editor of the Scientific American, 361 Broadway, New York etty" 8 The articles will be passed upon by a Hoard of
- 8 The articles will be passed upon by a floard of Judges, whose names will be announced in a future issue of the Scientific American
- 9. The Board of Judges will revelve only the articles submitted; the envelopes containing the true names and addresses of the authors will remain in the possession of the Editors of the Scientific Alagareas. When the judges have made their decision, the Editors will open the envelopes of the winning contestants and notify them of their success.
- 10. The decision of the Judges will be amounteed in the Peirstein America of November 1st, 1013. The prize-winning articles will be published in the order of merit in consecutive Issues of the Scientific American, beginning with the Issue of November 1st, 1013.
- 11 The Editors of the Scientific American reserve the right to publish in the Scientific American or the Scientific American Scientific articles which have not been awarded prizes, but which are deemed worthy of bosonvible mention.
- 12 While contestants are not required to supply pictures with their articles, illustrations will be council If drawings are submitted, they need not be elaborate, the staff articles of the Schrafter Amenica, will work them up for reproduction, provided the muterial supplied is intelligible. Do not send pictures ton from books and periodicals; they cannot always be reproduced and periodicals; they cannot always be reproduced and periodicals, and their unauthorized reproduction may conditute a copyright infringement. If photographs marked "copyright" are sent, they should be accompanied with the copyright on ser's written permission for their reproduction.
- Members of the staff of Munn & Company, incorporated, publishers of the SCHENTIFIC AMERICAN, and of Munn & Company, solicitors of patents, are excluded from the contest
- All articles will be received up to 5 P M., September 1st, 1913.

this week about the blood in disease.

# Dissecting a Military Dirigible Airship

An Interesting Experiment With the New "V1"

By Dr. Alfred Gradenwitz

N interesting operation was recently performed. A when the German dirigible "VI" was taken apart in accordance with military regulations, thus bearing out the designer's claims that the ship is a "knock down" craft

The aerial cruiser, which in appearance resembles a rigid already of the Zeppelin type, had landed in the vicinity of Julich. Her crew, assisted by twelve men, began on the same evening the detaching of the keel began on the same evening the detaching of the keel and the evacuation of the gas envelope. On the follow-ing day, the keel, consisting of steel tubes, was un-screwed, the virtuous sections being loaded on farmer's wagons, which by the following toon reached the Dis-sident airship shud. The distance covered was 33 miles. After a day's rest, the keel was replaced by the same crew. The whole performance spoke well for the remarkation success of this new military airship type.

type. The "VI" has been built according to the Yeeh patents and is of the semi-rigid type, combining, it is claimed, the individual advantages of the rigid and non-rigid systems and svoiding their draw-backs. The gas capacity is \$500 cubic meters, the length, about \$0 meters, and the maximum diameter, 18 meters. The main distinctive feature is a stated beautiful to the part of the part o indeters, and the maximum unmerer, is mevers. The main distinctive feature is a rigid keel frame constitut-ing a covered gangway limmediately below the envelope Easy access to all parts of the craft is therefore secured while under way, and at the same time an artificial stiffening is provided which does away with the necessity of any additional cars. This frame, which forms, as it were, the breasthone of the whole airship, not only permits the load to be distributed as desired (arranging e.g., the ballast and fuel in small tanks in any part of the keel), but insures an advantageous arrange ment of the steering mechanism, far away from the center of rotation at the stern, without overloading the

The envelope is a single large gas-compartment and is fitted with two auxiliary ballonets intended primarily to maintain the proper gas tension, while serving as well, in cases of emerg-

eucy, for changing the att. The shape of the gas bag is preserved in the usual way by two self-con-tained centrifugal blowers, means being provided for each venthator fan in be driven from one of the two both the fore and aft bal-lonets. The blowers and gas hags are controlled by the pilot. Hand operation has likewise been provid-

Normal steering in a vertical direction is effected by means of planes arranged like Venetian The keel is strong enough to carry without any support the weight of all planes, with an ample

#### Gas Engine Yacht By Robert Macintyre

THE vessel pictured in this article, is a proper to the proper several respects unique. Whe is "Y Ddraig Goch," which is Weld for "The Red Dragon," and was built on the Clyde from designs by Mr. William Gray, a well-known British naval architect, for Mr. Godfrey Williams of Aberpaym. Mr. Williams is a wealthy Welshman who has inherited from a long line of bearers of his name iands in South Welse which are rich in coal, especially anthractic. His bobby is ocean crusting, and he has in his day owned more than one large yealt. None of these quite pleused him, however, so he set about the formulation of his requirements and handed the result over to Mr. Gray to be embodied in an ocean-going yealt. "Y Ddraig Goch." is the yacht.

Rigged as a four-musted fore and aft schooser spreading some 20000 square feet of canwas, excluding bulloon suits, she is 200 feet long, 38 feet brand, by 21 feet 6 inches deep, displaces 1,000 mas, and measures 1,000 tone trees. The arcommodation for the ewiver and his friends is artistically decornized and elegantly furnished, the furniture consisting of reproductions by a Ludoni West End fran, of exhibiting examples of the period of Willliam and Mary. Most of it is in wahnt the dining room is in white commed with pushed depicting ancient ships. The drawing room is framed in wahnt. Elsewhere, except in the chart room, white is preferred, an excellent effect being obtained in the children's room by adorning the puncles with defleately traced pictures in pale blue of hunting scenes in olden times With all this selegance of accommodation

William recent of the "I Darrie Goth," finished in white enamel

Drawing room of the "Y Ddraig Goch," framed in walnut.

"Y Merity Goch" combines the structural strength of a mercautile ship. She has isen built, indeed, to Lloyd's highest class for solling ships, and in excess of the requirements her main deck being for the greater part of its length watertight. She is the intracts motor mutilitary yacht ever built in fairopean waters, and the first of any slot to be propelled by means of a gas cagine. The power for her motors is produced on board from anthractle coal, of which she can carry in watertight bunkers sufficient to take her round the world motor power slone. As the fuel is used the bunkers are utilized for water ballast.

The main propelling engine is a sixcylinder type of 100 brake horse-power, and it drives a feathering propeller through a clutch. A less powerful fourcylinder engine of the same make drives a dynamo which provides the power for lighting the ship and working the deek machinery. In order that there may be no need to use this smaller caughte at night, a secondary battery has been fitted, which is equal to the work of the whole of the ship's plant for twelve hours. The main engine can be disconnected from the propoller shaft and need to drive an nuxiliary dynamo.

The vessel is heuted and vontilated by means of theorematics, which are, in this lineauce, and for the first time if a yacht, adapted to the me of sen water in tropical climates. The temperature on board can never be more than 2 or 3 degrees in excess of that of the sea water. Nothing which the owner's experience of senfaring could suggest has been left unprovided, down to roller reeding zen on the booms. The yacht, which is now cruishing in West Indian waters, has proved herself to possess flue weatherly qualities, and her gas Plant has so far given excellent results.

#### One-piece Steel-end Freight Car

STREIL is rapidly displacing wood in the construction of railtroid care-moin only in passenger cars where the safety of the passenger cars where the safety of the passenger is an important consideration, but in freight care as well. The accompanying liberation shows a freight car, the entire end of which is made of a single place of steel pressed with concentration and a single place of steel pressed with concentration and a single place. Not only is at stronger than a built up end would be, but it keeps the car in alignment and allows, furthermore, an additional foot of space within the car. The end piece is applicable to any class of car old or new, as it can be made in different sizes. It is fastened to the rest of the car body by means of boits or rivets which pass through flagses at the edges, which pass through flagses at the edges.

#### The Origin of Screws and Gears

REMONT, in his recent work on the origin of screws and genrs, brings out interesting points on this subject. The Greeks are supposed to have invented the screw, but the two Roman authors, Pliny and Vitruvius, give the most ancient record we possess on the subject, although it must certainly have been known long before their time. Certain authors think that the idea of the screw comes from ob servation of a natural object of helical form such as a gasteropod mollusk, but Fremout thinks that it arises from forms in movement. For instance, when an edi-ble snall is drawn out of its shell, we have the idea of screw and not. Unfor-tunately the ancient records throw scarcely any light on the subject. The principle ly any light on the subject. The principle of the screw seems to have been but little used until the middle ages, when it was first applied for wine or cider presses. During the first centuries of our era

During the first conturies of our erabolt and nut was replaced by threadless bolts having a hole containing a conical juln, so that driving in the pin increased the pressure; such bolts had holes spaced along for adapting to different thicknesses count for the origin of gearing. This seems to have been a wheel working on a horizontal shaft and operated by a creak. Along the wheel surface were clear for retaining the broket chain which descended into the well, and in this way the buckets were raised, one after the other, full of water. But to drive the sories by an animal makes a vertical shaft necessity, and an ingenious person may be extended the clears on one side is the same contained the clears on one side is the same contained the clears on one side is the same contained the clears on one side is the same contained phase placed as a vertical state; to

# How Insects Fight

Stings, Mandibles, Horns and Poisons in Warfare

By Percy Collins

The grotesque rear-horses or mantids in combat.

About one half natural size.

MOST animals fight when occasion demands, and Indeed, many insects must be regarded as accomplished warriors, equipped with weapons of uncommon efficacy, and versed in all the strategic arts. Those who have and versed in all the strategic arts. Tunes who have puld attention to the warfare of insects are aware that that epotests may usually be classed under one of three headings: they are either (1) purely defendive, or (2) an outcome of the courtain instinct, or (3) definitely aggressive. Certain insects, however, appear to labor under the influence of a veritable mania for battle Amoig these are the well-known reer-horses, or man-tids, whose fore legs are so remarkably modified to act as reptorial implements. With these terrible limbs, which are binged and spiked in such a manner as to combine the attributes of the flail and the skark's teeth commine the attributes of the mail and the skark teem sword of the Pacific blanders, cent-horse capthre and hold their prey; but they are also used as weapons of offence and defence. It is said that two rear-horses scarcely ever come face to face without fighting. Moreover, the contest is not merely a display of skill, but n duel to death. Sooner or later one of the combatants gains a momentary advantage, and seizes its opponent This puts an end to the battle; for the victor never releases his grip, but begins at once to make a meal of his opponent. Nor are these affairs confined to the members of one sex. The femule rear-horse often, if not usually, tires of her accepted suitor; and when this happens she rushes upon him with menace. The male attempts to defend himself, but as he is smaller and less robust than his spouse he is generally defeated Subsequently, the female calmly devours her quondam mate. Beyond these conflicts for prey the mautids are

Among the jursty defender appliances of insects none is more interesting than that possessed by the so-called bombardier bestiew of the gaune Bruckinson. These insects are carnivorous, and destroy small Arthropods of various kinds: but they are themselves preyed upon by larger beelles of their own family. When one of the hereditary sensite gives chose, the bombardier runs rapidly away. If speed were its only chance of escape, however, it would stand but a post chance. But nature has endowed it with a romarkable defensive equipment. It is able to oper an acid finish from glands situated at the tip of its abdomen. This find vaparities immediately on contact with the air, and looks like a tiny puff of smoke, while at the same time a datafort report is heard, reminding one of a miniature cannon. The beetle is able to repeat this discharge several times in rapid succession before its store of amminition becomes exhausted. In this way the little artilleryman is able to disconcer its would be captor, and very often contrives to rush into a ranno, or under a stone, where the enemy cannot follow. The acid discharge of certain large South American bombardiers is extremely counted. It turns and stains the human akin, leaving marks which remain for a considerable time.

for a considerable time. The most formidable weapon possessed by insects is the polson sting. It is only found among the hitcher hymenopters (i. e., insects of the bee and weap kind), and is confined to the femnie sox, heling, in fact, a modification of the originate of the original papers of the original confined to the femnie sox, heling, in fact, a modification of the origination, and is present a parts working in conjunction. There is a growed and pointed shaft, along which silds two darks, more releast barbed. The shaft is first used to open a wound. Then the dark are plunged eiternstely into the tissues, while an acid secretion flows down from the poison-sac. Like been and wangs, some species of ants are equipped with stings, but others lack these weapons. The polson-sac serves merely as a received whence formic acid is squired from an orifice at the tip of the abdomen. These stingless auts, therefore, first bite their enemy with their jaws, and then spray polson into the wound —a somewhat cumbersome method, involving two separate and distinct operations. But ants are very saffe, while the extraordinary factibility of their weals" (i. e., the poglou between the thorax and the abdomen) canbies them to direct their poisonous discharge to almost any points of the compass, Moreover, stincing and points of the compass, Moreover, stincing and the standard, the sould be standard, the straight samples of deviations, and dept their formic services.

acid into the air. The pungent fumes tend to disconcert and drive away the enemy; and there can be no question that ani-battles are often won without the indiction of a single wound.

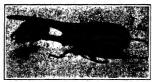

Ants are probably more aggressive than any other insects. They constantly make rules upon noithworing mosts, and pillage the stores. Some species, as is well shown, Actually engage in comparigate for the sole purpose of obtaining a supply of slaves. Slave-making auts nountly attack the communities of species smaller than themselves, and after terrorizing or driving out the shall inhibiting, carry of all the grabs and impre-

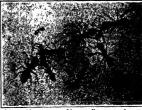

East Indian male beetle with developed forelegs for arresting the female.

The acid discharge of a bombardier ant disconcerts

The giant hercules beetle carrying off its mate.

Slave-making ants attacking smaller ants and carrying off pupas.

Male stag bestles in courtship warfare. The victor

that they can find. These they convey to their own and when the mature and appear, they are caused to play the part of domestic drudges in the post of their cuptors. The slaves prove themselves industrious and docile, and it is a remarkable fact that, although they are apparently free to come and go as they please, they never attempt to escape. It has been proved that certain ants are completely dependent upon their siaves. They are fed, cleaned and even carried about by their indefatigable helpers, and if by chance they should be deprived of this assistance, they abso-intely refuse to cal, and soon die. One rare European aut has no worker caste. After mating with a mule, the female obtains access to the nest of another species. She then kills the rightful queen, and (by what arts has not yet been discovered) contrives to ingratiate herself with the worker population. The last serve their new inlstress faithfully and lend her offspring; but as no more worker eggs are laid, the prosperity of the kingdom steadily declines. Before its that dissolu-tion, however, the alien queen will have become the parent of a numerous progeny which will saily forth at the appointed season to accomplish the downfall of other nexts. The usurper and is called Incomates atta-tulus, while the species which it victimizes is Tetramonium caespitum

The contradity warfare of mule baseds is especially interesting. Among the "State feetlers" of the family Lurander, several mules often light desperately for possession of a female, buffetting one modules with their enormously the edged namidities, and exhicing no little skill in their methods of allack and of defence in the heliahl of the breeding season, these lunests are so much occupied with their rivalry that they seem to lose all senses of fear. Thus, a cuntion solective may often witness the duels, and even obtain photographic records of them. In the presence of a female, two male stag-levelies have been known to fight upon the surface of an ordinary table, before the lens of a consense, and the season of the season of the season of the female with the family and push of carry her to a

In many cases the strangely shaped "horns" which are carried by seurable beetles upon the head and thorax appear to be specifilly provided as implements for holding and translocating the female. The mildry Hercules (Dipantis heruch)—one of the hirgest known beetles has been seen to carry off tils unter he this was, after having won her in fult fight with his rivals. The nucles of other heetles, such no the species shown in the necessary in the protograph, have specially developed forcelinate for ransping photograph, have specially site should prove cov at now time and attempt playfully to run away.

Scorphone are not insects, but they are sufficiently close in relationship to be included in the subject of this article. But are most interesting creature in captivity, and if several specimens are keep their meli-node of warfare may be studied. In the photograph reproduced herewith, the right-hand scorphon has seduced a cockroneth, and historiand scorphon has seduced a cockroneth, and historian defensive attitude, prepared to fight for its booty with a hungry rival. Note the cuttons advance of the batter, with independence of the stage and their way of the stage and the stage of the stage and the stage of the stage and the

#### Blondel Becomes an Academician

THE French Academy of Sciences recently elected to Arabel Prof André Bludel as a member in the place of the deceased savant Callietet. This well known selected is expected by the place of the several by the electrical field, and he occupies the first rank among electrical physiciets for his researches upon electrical waves, resonances, synchronous undoes, photometry and the like. What is remerkable is that he is bed ridden for the last ten years, and directs his pupils and assistants in the constructor of the electrical apparatus which havents, among the most remerkable of these being the oscillograph for observation of the forms of electrical waves and their photography.

## The Motor-driven Commercial Vehicle

This department is devoted to the interests of present and prospective owners of motor trucks and distoury imagens. The Batter wall emissions to automate any questions relating to mechanical features, operation and management of commercial motor vehicles.

Hook-and-ladder truck hauled by a gasoline tractor.

#### Advantages of Tractor Transportation

IN the early days of practical motor trucking, which, incidentially, were not so far back but that they are easily isrought to mind, it was by no means a trivial matter to construct a machine that would operate consistently and economically under normal working conditions. If a truck would do what it was built to do it was silt that was expected it did not take long, however, to discover that the lond actually carried on the londy of a truck did not call for the evertion of anything like the normal power of the motor under ordinary minding conditions, and that a radier, coupled up behind the loaded truck, cauld well earry a very substantial separate lond and be hauled at reasonable speed without over-taxing the motive power, though of course, the hill-climbing ability of the machine would be

correspondingly curtailed.

Some idea of the londs that can be handled in this way may be gained from the fact that is shadord fleven truck has handled a trailer fond of 45 tons, including the trailing while, and even this does not represent the greatest weight that has been trailed by a five-ion machine. Obtying such a powerful transportation system could not well be neglected, nor has it of late years the trailer principle, with various modifications, has received much attention and excellent results are being obtained in actual covery-day work.

Five-ton truck with a lumber trailer.

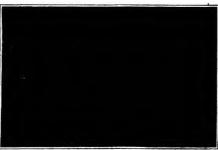

Gas-electric tractor; a motor in each inclosed wheel.

While in Europe the warou train, consisting of a tractor and several trailers, has been quite extensively developed and employed, in this country more attention has been given to what may be termed the semi-trailer system. Briefly, the semi-trailer unit consists of a motor truck, usually having a short-coupled chansle, carrying a sort of fifth-whoel or turntable on which is mounted the forward end of a two-wheeled trailer; the whole of the load is carried in the body of the two-wheeled trailer. By calculation as to the position of the turntable on the chassis and on the trailer whoels, any desired distribution can be effected, and the noit has the advantage over the ordinary truck-and-trailer outfit that it occupies considerably less space, is more easily maneuvered and is less expendive to construct. The rear wheels are of ordinary wagon construction with steel three, though it is necessary to employ considerably heavier wheels than would be required for horse trucking because of the increase of speed and the high mileage obtaining with the use of power.

The steel-tired rear wheels, coeting, as they do, far less per mile than the rubbertired wheels of the truck proper are made to carry the greater part of the lead, the weight on the chassis being just sufficient for good traction. This makes it a simple matter to proportion the lead on the rubber tires we that they will work under

(Concluded on page 270)

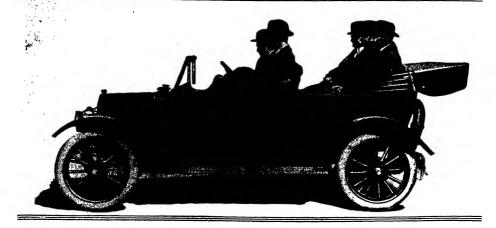

Motor truck with short-coupled chassis and two-wheeled trailer.

Three-wheeled electric ask cart.

# A Real Automobile For \$750 1914 Maxwell "25-4"

# This is the car you've heard so much about!

This is the car you've been waiting for—the car competitors said we would never build at the price.

It's a real automobile, too. Power plus; 103 inch wheel base, Tonneau 44 inches inside the cushions—same as our and other 35 horse power cars. Same size tires all round—30x3½. Weight under 1600 pounds. All the speed, hill-climbing and mud-plugging ability you'll get in our larger car—relative power and weight in favor of this model, if any. And better workmanship, better materials, do not enter into any car on earth because we use the best.

You can now see this car by calling on any of our large dealers. Smaller dealers being supplied as rapidly as possible. You'll have to wait for your car, thanks to tremendous overdemand. But get your order in now and you'll get your car that much sooner.

# Dealers' Special

4,000 dealers will handle this car for 1914.

Heretofore we have declined to sign up with so many because we could not furnish the cars.

We are now under way. Factory capacity will rapidly increase. We are laying out our plants for 500 cars per day of this model. Can't reach that in a day of course. But this means that within 18 months we will be the largest producers of light touring cars in the world bar one.

And, as we said, this is a real automobile, with 3 speed, sliding transmission and other features that you know as standard in high class cars. Looks the part, too, and that's an item.

In short, this car is designed for buyers who must consult their purse and yet who are willing to pay the little difference for a car that is worth a lot more.

We are ready to sign up now. See and try the car—our District Manager and Distributors in your territory will show you and tell you what territory is open.

#### Advantages of Tractor Transportation ded from page 168.)

favorable conditions. It is known that a truck of this type, having a capacity of months on a single set of tires, and ever then only two were unfit for further ser vice, the two front tires remaining in ser vice for four mouths after two new rear tires were applied. This of course results In a very marked operating economy, as tire expense in heavy trucking is a seri-A machine of peculiar design that ha

been evolved especially for service as a tractor has but three wheels, the two in the rear being drivers and the single front wheel of course the steering wheel So far as the rear end of the tractor is concerned, it resembles the ordinary type of gusoline truck with final drive through sprockets and chalus, and the mo-tor housed in the conventional bood with the radiator in front. The single front wheel, however, serves to give the machine a decidedly unusual appearance. A forward extension of the frame—or, more correctly speaking, a separate steel custing riveted to the forward end of the main frame—carries a socket in which turns the shauk of a heavy fork straddling the front wheel. The fork structure is not continuous to the wheel indi, but on each side there is a full ciliptic spring which provides an elastic suspension. Steering wheel which is connected to the top of the fork pivot through a long shaft, which passes over the top of the motor hood, and reducing gears contained in a casing at the top of the socket. For service where conditions affecting traction always are good this tractor is fitted with steel tired rear wheels; more commonly, how king-rdn and jurntable upon which the front end of the truller member rests are directly over the rear axle; the axle and wheels of course are proportioned to carry the load, while the front wheel is loaded only sufficiently for steering purposes, and its load is practically constant, regardless of the weight curried in the trailer body

For some years the gasoline-electric or mixed system of propulsion has been h hicles of this type, with four-wheel drive and steer, have been successfully put into service as tractors and semi-tractors. Iu one such machine the engine, mounted under the floorismrds and the driver's seat, is direct connected to a generator, which supplies current for four electric nuctors, one being inclosed in each of the steel disk wheels. Each motor is, in ef-fect, part of the stationary axle and its armature remains in a horizoutal position while the wheel rotates around it. Each end of the armsture shaft carries a pin lon, and each pinion meshes with a large genr ring on the Inside of the wheel, clo to the rim. The armature necessarily is slightly skewed so that the pinions can singuity skewed so that the pinions can nesh with opposite gear rings and thus both drive the wheel simultaneously. An equalizing device in the armature shaft permits slight relative movements of the pluions in the manner of a differential Kenr Vehicles of this type also are fitted with batteries, the battery machines being suitable chiefly for comparatively short

distance service A tractor with four-wheel drive and steer, dividing the work, as it does, be-tween all four wheels, requires a differcot distribution of weight from a rear wheel driven machine. Therefore turntable carrying the front of the body ls so located that the rear wheels receive but little more weight than the front wheels. The advantages claimed for this arrangement are that as all work is divid ed between four tires, no one or no pulis overloaded or overtaxed, but rather, all are working under favorable conditions. Further, the four-wheel steering system is said to facilitate maneuvering in close quarters and running in the reverse. The convenience of electricity as a motive power for auxiliary purposes has led to the installation on these trucks of a number

of electric hoisting bodies, winches and the like.

While a short-coupled chassis such as

While a short-coupled chassis such as in used in both the cases referred to usually is been dapped to semi-tractor work, it by no means follows that a long or standard chassis will not answer the purpose. On the contrary, not a few standard ister trucks are employed, either standard site trucks are employed, either model of your inventions and selections. One of the purposes to which they are particularly well adupted is the handling particularly well adapted is the handing of long timber, which cannot be mounted ou a single body and, besides, often is of greater weight than can well be carried by a truck that may be well able to haul on a trailer.

One of the niches that the semi-tractor has filled very satisfactorily is that of mo-tive power for very heavy fire apparatus, the horse-gear and front wheels being re-moved and the front of the apparatus mounted on the turntable of a semi-trac tor. The great weight of these pieces has made them clums; and slow-moving when herse-drawn, besides being capable of mov lng only forward, in m plication of the semi-tractor has convert-ed them into modern motor-driven machines at a cost far below that which would be incurred in building complete new pieces, of similar design but with mater propulsion built in. Water towers, hook-and-ladder trucks, steamers and other types of fire apparatus have been equipped to this way, and many such are in constant service

Front wheel drive, which of course em-

holles the tractor principle, is receiving for more attention at present than it has In the past, largely, no doubt, because me where the difficulties that formerly were or less buffling can be overcome. The electric systems, with motors mounted as units with the wheels, are readily applicable to front-wheel drive, but there also ure several mechanical driving system that inve given good results. French system, for instance, which is being introduced into this country, show the capabilities of the principle A motor with transmission gearing, change-speed ed on a pair of wheels, together with the driver's seat, gasoline tank, radiator and so on. The tear end of the short is extended in such a way that aim . The tear end of the short frame is sort of body can be bolted in place, the body of course having its own wheels, which may be, and preferably are, if econconsideration, of the ordinary steel-tired type. The weight of the power plant is so behaved that the body has

Drive from the vortical four-cylinder motor, which is placed in the conventional position, is through a cone clutch and a sliding gearset operated in the usual manner. Flual drive is through a cross shaft which carries spur pinions meshing with sour genra bolted to the wheels. Universal joints located in the planes of the steering plyots permit steering and drivlug at ouce. The gears are of course lu closed as well as the cross-shaft and its joints; incidentally, there also are universal joints where the shafts emerge from the differential housing, so that all possible disaliguing strains are provided

employed in a machine that has the dishas been built in this country, and is used by the railroad company that constructed city streets where a locomotive is imprac-ticable. The huge tractor, which drives and steers through all four wheels, de-rives its current from a storage battery und weighs fourteen tons, has a moto for each pair of wheels, driving through reduction gearing and cross-shafts universally jointed. The joints are peculiar in that they are inside the pinions in er words, the pinlou forms the outside of the joint. Obviously the pinions are directly in line with the steering pivots. Steering is effected by means of a wheel of the marine type located in a can that of the marine type socsed as a can be made action the has the appearance of a regulation that facety in Rife the boat pilot house.

Still another application of the front wheel drive system is found in the conversion of the two-wheeled ash carts that are familiar in most large cities to bat tery trucks. A heavy fork, with geared steering mechanism, is mounted with a wheel in which an electric motor is in-closed, the wheel being similar to those in the electric tractors already referred to. The construction is extremely rugge is necessary with the class of drivers that must be put on ash and rubbish carts, and there is nothing that exposure to the weather can affect lujurlously.

The Fire Convention at New York THE annual convention of the Interna-tional Association of Fire Engineers, which assembles in New York city during

the first week of September, will be of interest as emphasizing both the import-ance and the status of the fireman and the fire department in present day American life

Aside from the glamor of excitement and heroism which always has been con nected with the profession of fire-fighting, there is now an economic and engineering side that is becoming increasingly promi-nent, so that the modern fireman with nent, so that the monern bremain with motor apparatus, high-pressure mains, spe chal permanent equipment within lofty tower buildings, fire drills in crowded fac-tories, and other twentieth century conditions, not to mention his work in securing proper and safe building and maintenance, is a very different person from the roughand-ready worker with undaunted physi-cal courage of a not distant past. Indeed, in the general awakening of interest in conservation and municipal efficiency, the freman is not the feast concerned, for he of all public servants realizes that his true rôle is not the horole fighting of spectacular and devastating confiagrati

but the prevention of all outbreaks of fire. Unfortunately municipal authorities, unwilling to lock the door until after the theft of the borse, too often fall to give proper attention to the demand of the fire man for adequate equipment and to his suggestions for effective building regulasuggestions for enective building regime-tions and the enforcement of safe condi-tions of maintenance. One has but to at-tend such a convention as this to realize how earnestly the better grade of fire chiefs are devoting themselves to the lmprovement of building methods, and how they are according the engineering as well as the practical knowledge now demanded in their profession. It is in this connection that the coming meeting in Ne tion that the Comma accretion with the professional papers presented and discussed in formal session, for it will be held in a city where the technical side of fire-fighting has been highly developed Here a fire college is maintained for the instruction of officers and men of all ranks, an institution by the way which not only is being copied, but is utilized for training officers of other cities. In this fire department, motor equipment has been developed not for racing but for practical developed not for racing but for practical service. A high-pressure service and a large flect of powerful fire-basts have made a very widespread confiagration practically impossible.

All of this represents n branch of muni-cipal engineering of a high order. The same problems are also interesting other cities, so that the fire chiefs from the cities of America, Canada, and Europe, much to see as well as much to give from their own experience. Not only will then be demonstrations of equipment and meth ods in addition to a large exhibition in the Grand Central Palace, but an elaborate series of practical tests of apparatus from many manufacturers carried on by mechanical engineers so as to secure comparative and valuable rest

# A Truck Tire Service Supremely Good

Special Firestone service stations—for users of motor trucks—are located in all the great cities of this country.

Firestone Tires not only increase truck efficiency, but this special service provides a system of prompt and complete accommodations appreciated by every truck user.

Then in the smaller cities—in every village and town where a truck is found—the courvalent of such service stations may be enjoyed in the form of the Firestone Removable Rim Equipment. This practically gives service station advantages to any truck user, anywhere. The

# Removable Equipment

for Firestone Truck Tires is all built to S. A. E. standard—with parts interchangeable—all at your service immediately. Your truck tire equipment—no matter what it is now—can be changed to Firestone without much loss of time, and to your decided profit in wonderfully improved tire service.

Firestone Removable Equipment insures against annoying delays—gets for truck users the very closest co-operation in meeting and overcoming all tire problems. Firestone Removovable Rims passed the experimental stage long ago. Years of service have proved their success in abolishing truck delays and lay-ups for tire repairs. They are not complicated. Any driver can easily make a replacement in a few minutes. Truck users need the values of

# Firestone TRUCK TIRES

Hard Rubber Base Channel Type

More than any other part of the truck, tires are affected by all the abuses of everloading, rough pavements, careless driving, etc., as well as by the grind of day-to-day traffic.

To prevent time losses—money losses—Firestone Truck Tire service gives quick replacement facilities.

Firestone Dual Notched Tread—shown in the large illustration—supreme for heavy service. Overcomes the bulge, or traction wave, that tears ordinary tires away at the base. Increases mileage, saves gasoline, reducestruck upkeep. Cured in Firestone Quick Removable Rim, thus insuring perfect seating.

Single Side Wire-Channel Type

Firestone Channel Type—Hard Rubber Base—on Firestone Quick Removable Rim. Has dense, tough tread built on a hard rubber base and cured in saw-tooth channel the sides of which afford protection against side abrasion and add strength to the union between rim and tire. This is an exclusive Firestone feature. This tread is built up of thin layers of sheet rubber and then cured into a solid unit. Resiliency is just right to protect the car. Insures maximum mileage under the heaviest service that can be put upon it.

Firestone Side Wire—Removable Block Tire—the recognized standard equipment for heavy motor-driven

or horse-drawn fire apparatus. Firestone quality of rubber and merits of the Firestone side-wire fastening device have placed these tires in their commanding position. They are increasing fire apparatus efficiency and reducing its maintenance cost in more than three hundred progressive American cities and towns.

European Type Dual Hard-Base — European Type Hard-Rubber Base — these and all other Firestone Tires for thorough truck service present a superior quality of rubber and all materials, and a general character of the highest standard. Your truck tire questions will find quick, easy and profitable solution in "Firestone."

# The way in which the world is receiving the 1914 Cadillac, the wonderful manner in which it is performing, presages an unprecedented Cadillac year

There never have been enough Cadillacs-there surely will not be enough of this new 1914 model

In the year closing June 22nd the Cadillac Company manufactured and distributed 15 007 cars

Several thousand buyers anxious to own Cadillacs were compelled to be content with other cars

It was the story of the previous year all over again in spite of increased production

And the story of the year before-and the year before that

Each season the same thing has happenedthousand more Cadillacs could have been distribu ted had we been able to produce them

Intending buyers disappointed in securing Cadillacs have been numerous enough to constitute almost the entire clintele of some other cars

For 1914 we plan to manufacture 18 000 cars

It is perfectly obvious that Cadillac history is not only repeating but surpassing itself

Reports from all parts of the country make one thing perfectly plain, to wit That the accustomed Cadillac demand has been inten-

sified into downright eagerness This is due to evolutionary developments in the new car

Most potent among them is the marvelous influence of the Two Speed Direct Drive Axle

Every one who rides in the new Cadillac recognizes im mediately that its well known smoothness has been supplemented by an entirely new riding quality

This is demonstrated at once, even to the inexperienced

Going even at high speed the passengers discover that motoring in this new Cadillac has lost its sense of

Unless the eye is on the speedometer, one is apt to guess that the car is going at about half its actual rate of travel

Mentally and physically, driver and passengers uncon sciously relax, revelling in the delight of a new and luxurious sensation, oblivious to the almost watch-like mechanism

And on the heels of this delightful discovery come others equally pleasant

The owner finds that this Two Speed Direct Drive principle influences almost every Cadillac function which contributes to ease efficiency and economy

It not only brings into being a new degree of luxury but accomplishes an abatement of operating cost

The slower engine speed results in greater power gen-erated from a given amount of fuel

The slower moving parts means less friction

Both of these mean lower fuel consumption

But above all else is the contrast between the Cadillac and the average car with the ordinary gear ratio

The trembling oscillation of the latter is transformed in the Cadillac into a straight ahead steady motion which reduces vibration almost to the vanishing

A simple electric switch changes the gear from low to high and like magic there is added to any given speed of the engine an increase of 42 per cent in the speed of the car

Now-recall to your mind the high repute in which the Cadillac is held

Remember its record for workmanship almost miracu lously fine for strict standardization of its parts for alignment of its units

Remember its reputation for staunchness for dependa bility for long life and for the supreme satisfac tion and service which it renders to its users

Remember its reputation for economy of operation and maintenance

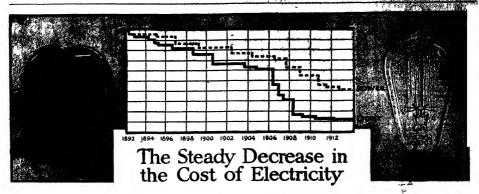

Remember the stability and the ideals of the organizi tion behind it

Consider all these things stimulating the rivalry for early deliveries

And then try to conceive the effect of this new revela tion of Cadillac progress added to all the others

You will realize then that we are acting in your inter est when we advise you to book your order now even if you do not wish your new Cidillac de livered for several months

#### STYLES AND PRICES

"They say you can prove anything with statis-tics," said the manager of a big Indiana manufac-turing plant to the Board of Directors, "but when the statistics are on your own books you can believe them. And the figures show that since we installed electricity, seven years ago, electricity is the one item of costs that has steadily gone down."

The manager was arguing for an extended application of electricity in the plant-and he won his

point.

This manager's declaration as to power cost was fully in accord with the remark of Thomas A. Edison in the matter of lighting. "Electric light," said in the matter of lighting. "Electric light," said Mr. Edison, "is the only thing I know of that has become any cheaper in the last ten years."

Why has electricity declined in cost when indisputable figures and the common experience of men show that "the cost of living" has been steadily

rising?

It is plain that many of the commodities whose increase in cost is chiefly responsible for the increased cost of living enter into the production of electric light also—coal, labor, and copper for example. From 1902 to 1907 coal increased 6½ percent. Within the same time labor advanced 81/2 percent. The cost of copper increased about 35 percent. Yet the cost of electricity went down as steadily as the cost of living went up.

Mechanical factors have had much to do with this reduction. In the first place the more advantageous placing of electric plants beside water falls or coal mines. Then larger plants and great improvements in transmission systems have played a

part. Improved generating systems, as with the Curtis Turbine Engine, and the cheapening of installations by new inventions, have added in an important way to this progress in economy of use. Inthis progress in economy of use. vention and price as factors appear in the case of light, for instance, when the sharp decline in cost between 1892 and 1898 was due largely to the reduction in the price of carbon lamps. New types of lamps effected a further reduction between 1899 and 1902, and the perfecting of the Tungsten and later the Edison Mazda lamp, which uses only one third of the current required for the old-style lamps in common use, has again lowered the figures since 1908.

A fact of specific and striking interest is that all

classes of users of electric light and power have not only shared in the reduction but have helped to bring

it about.

This has happened under the natural conditions of extended use. The wider use of electric power and light has enabled distributing plants to sell current for a greater number of hours in the twentyfour and in this way to reduce rates based on the twenty-four hour maintenance of the plant.
Thus in Chicago one dollar now almost buys

eight times as much electric light as it did in 1886, more than twice as much as in 1909, just four years ago. Another illustration of progressive conditions as they are shown in large distributing centers is Boston's reduction of over sixty percent, in a single

The results of methods of use as well as method of supply—this is the story of the chart on this page.

And in all this growth of electricity from primitive experiment to world-wide usefulness, the General Electric Company has played a leading part. Just as electric lamps have been developed in the G-E factories for all uses from the lighting of automobiles to the lighting of factories-so numberless types and sizes of G-E motors are now available for driving all kinds of machines from dentists' drills to massive steel rolling mills.

To know how electricity may fit your particular

business, consult your local power and lighting company, or any G-E dealer or agent in your vicinity. No matter how simple or how complex your problem may be, these agents have always at their command not apply-information of the latest developments, but also the co-operation of any part of the G-E organization that may be most helpful to them and to you.

#### Commercial and Military Value of the Intracoastal Waterway

THE economies and milliory advantages to be sained by the construction of the system of intra-constant waterways which is recommended to Congress by Brigadier (denoral Bitky), the Chief of Engineers, U. S. A., are so many and valuable, that we believe Congress, after mature deliberation, will be convinced that the \$80,000,000 necessary for constructing a 12-foot waterway from New York to Beaufort, North Carolina, should be appropriated

As matters how stand, the constwise reaffic, whether by water or rail, to being carried effice by oven-colons ships using the outside deep-sea ronic, or by railway systems which are approximately parallel to the coasisips using the outside deep-sea ronic or by railway systems which are approximately parallel or the coasisips of the coasis of the coasis of the carried or an inter-coasisi waterway, it must be shown that a vertain portion—a sufficient portion—of this trailic can be carried as safely, more expeditiously, and at leaser cost by the proceed canal. The opponents of the cann claim that the carriage of freight can be done more economically under the present method by occur-going seam and sail vessels and occan-going larges under tow, and by the existing milways. As regarded the question of safe transid, the statistics of the mount losses of life and of ships and their cargoes in the coast-use trade prove that they are enormous and show no signs of dimination. To reduce those losses, canalysis we seeds are built more stoutly and at much larger cost than those which has interior water routes. Thus occan-going resolute out \$45.50 pc. ton, and the Misoshoph River tag with barges for 10,000 tons of freight, cost only \$12 per ton, Parthermore, the expenses of deep-sea carriage are becomes of the part of the market because of 4 per cent on vessels using lander routes of \$1000 to the control to seed to the delay due to wind and weather.

A review of these facts in the report of the Chief of Engineers, made he January, 1912, leads like to state that the advantages of metastion by interferor over outside routes are such as, in general, to justify the opening of interfor waterways, a conclusion with which we was in hoursy agreement.

the the question of the relative economy and conce of transportation by infand waters approximately parallel rajiways, it should be carefully noted that any deductions, drawn from previous experi euce, in which inland waterborne commerce hus de clined where it has come into competition with railways, are liable to be very mislending. the solley of the rullway to make discriminating rules ig the service by rail at poluts where comp tition with water routes was possible, and making in points which were not favored with water r pay the cost of such competition. The work of the erstate Commerce Commission and the prean enlightened public opinion are removing the burden of discrimination; and it is certain that if the Federal Government constructs the proposed intra constal waterway, it will see to it that the new route is effectively protected against any such burdensouse rate dis crimination.

The report of the Army Engineers draws attention to the facts that it has been a policy of the railway companies to obtain possession, as far as possible, of all available wharf space in terafinal cities, partly with a view to, presenting campellion; that the railways have thrown obtacles in the way of dividing a long-distance hand between rail and water, so as to make an all-rail curriage most advantageous. This has been done by plecing difficienties in the way of transfer between rail and water, by refusing to honor through bills of lading over a fixed rail-and-water route; by making charges for short hauls by rail and distribution from water terminate prohibitively high. If the fall benefits of improved waterways are to be obtained, belt the nation and the Nater must take such action as will insure rail cooperation between the companies operating by rail and by water. Nor must it be assumed that the opening of the intra-

Nor must it be assumed that the opening of the intracuents waterway will openine to the disadvantage of the milways. Experience gives reason to expect that liners will be a division of the freight based upon its character, the changer freight curried in bulk going to the water route, and the expensive freight onling for rapid carriage gravitating to the rallways.

rapid carrange gravitating to the ranways.

The results of rail and water competition in Europe, where the count and novignide river mileage is encount, shown that the one system be not indiminate to the toterests of the other. Thus, in Germany we find that the large system is not indiminate to the toterests of the other. Thus, in Germany we find the latter of the

On the question of the military value of the lattracustal waterway, the report of the Army Engineers robust to the well-cetablished principle that for the decise of a fortifer threatened by an attack from without at some unknown point, the forces for the defense should be concentrated within the frontier line, at some unknown point, the forces for the defense should be concentrated within the frontier line, at south from which they can move rapidly and safely to the actual point of attack when developed. The proposed waterway between New York and Norfoth is resolutional to the Army Englances to form a mod desirable line for such movements of troops, bying as it does for its entire distance under the shader of fortifications balli or planned for the defense of the coast. Furthermore, it is above, for the defense of the coast. Furthermore, it is above, for the defense of the coast. Furthermore, it is above, for the defense of the coast-live units will be multed in a single carrier; there are defined to the consideration by rail. Thus, larger administrative units will be multed in a single carrier; there are defined to the consideration of the coast-live and of the coast-live units will be multed in a single carrier; there are defined to the consideration of the coast-live and of the coast-live units will be multed in a greater freedom from ordinary delays of transit. For the transportation of a division of troops there would be required, by rail, for a division of froups by water would require the services of only 22 ellips of the size of the "Monume" of the

Southern Pueffie Company, which has a 16-foot draught. For mural purposes, the intra-constal universey presents the udvantage of an additional and protected entrance for each of the ports from New York to Narfolk included—an udvantage, says the report, which would make impossible an effective blockade of any one of those ports.

#### State vs. National Control of Public Forests

The well understood by those who closely follow the course of hegistation in Congress intel awa are excessionally intered on the trature books which shittensh they early the appearance below held which is concessed a positive senace to the materials within the concessed a positive mence to the public good. Of such a character, we do not head to the many in the quiet but fundamental satistics which is now at work in favor of transferring our public forces from national to State control. The arguments in favor of this tennifer are plausible, but specion—a. East which is well understood by the friends of forcestation, who are straining themselves to the utmost to prevent the passage of an act which would prove to be one of the most potent agencies in exploiting by private interests what is left to be medium for our materials forcests.

agreement asymptotic in the public of our national forests.

Although the issue is presented as one of State versus authoral control, it should be undarstood that the utiliante if not the present object of this movement is the substitution of private for public ownership. The surest protection and and private exploitation is to maintain the control of our forests in the hands of the Federal dovernment; for it is evident that the compiracy of an individual or of a collective body of men for the control of timber land would be more likely of success, if it were carried on in a State Legislature than in the halis of Congress itself.

trol of immer latte would be more likely of success, if it were carried on in a State Laglajature than in the halls of Congress itself.

The argument against State control is well stated in a recent jamphlet issued by the Oregon State Conservation Commission, and the reasons set forth conservation Commission, and the reasons set forth conservation Commission, and

ing from a State a large area of white is covered by forcet land has a special suphtable. The Commission starts out by laying down the bread proposetion that the National forests are the property of the aution at the National forests are the property of the aution and its argues that, if the nation is caulied upon on you take property outright to the State, then the backen is on the State to show how this great truet is to be administered so that those for whom it is granted will be lettle or even as well protected than they are now in their rights in and to it. Judged from a national standpoint, build the state of the property furnish immer and other timiler products. They have other functions and ness which extend fur beyond State lines and involve the welfare of many people extentor of the State, since they cover and protect the headwaters of streams used for naviantion, irritation and power, and to some extent unbinder distances from the protect the restrict of the conice and then have a beneficial effect which are just bounded by State lines. They retard soll creation and this have a beneficial effect which may be felt for hundreds and even indirectly for thousands of miles from the rection queved by the forests themselves.

miles from the region covered by the forests themselves
At present these national forests are under control of the Federal Government and the cost of their protection, about \$4,000,000 a year, is paid from the na-tional Treasury. In the State of Oregon atoms there is expended in this work about \$480,000 a year, an amount which is approximately one sixth as great as the State's total expenditures for all Governmental purposes this must be added the sums expended in actual fire fighting, which, in destructive sensors such as 1910 and mounted to from \$75,000 to \$112,000 additto Now the State of Oregon has recognized the value of this great asset and the consequent obligation impo and it has worked in the closest co-operation with Federal agencies and private owners. The people of Oregon take the collightened view that the State, to-day, is in a better position than if it owned the forests. As matters now stund the protection of the forests is paid for by the Federal Government and the State celves 35 per cent of the gross revenue. Moreover, the experimental work, studies as to use of timber, etc., from which the State receives the full benefit, are carried on by the Government. It is estimated that whenever a tree is felled and transformed into lumbs per cent of the receipts are left in the hands of labor per cent or the receipts are set in the mans of many and those furnishing the supplies. "It is to be assumed," the Commission asks, "that the State management will be more efficient, less expensive and more satisfactory than that of the Forest Service?"

#### New York the Leading Port of the World

T will be a matter of surprise, perimps, and certainty of some poissons, to the citizens of Nor York, to learn that the very latest estimates of the value of the exports and imports of the two distort that New York town stands at the fend of the 1st, with an utwantage of nearly two bundred million dollars over Landon. Our contemporary, the data in Nortice, realish us that New Yorks total of exports and imports, new valued at \$1.973. OSLOBO is over five these the amount of commercy what was curried on by the earlier country half a

As in the future, there is one dominant factor, the Pamanan Cand, which is bound to strengthen the lead now secured by this port, for the canal will bring New York 1,000 miles monrer to Yakobama than is Liverport, 2,500 miles morrer to Yakobama than is Liverport, 2,500 miles morrer to Yakobama than is Liverport, 2,500 miles morrer wellington, New Zerhand, and 2,574 miles morrer Valuration. New Zerhand, and 2,574 miles morrer Valuration. New Zerhand, and 2,574 miles morrer Valuration. The new conditions—the general re-arrangement of trade routes—will tend to strengthen the position of this port in this supermeety over its nearest competitor. Expressed in round militions, the returns in millions; Harabara, 1,674 millions; Harabara, 1,674 millions; Marselles, 478 millions; Marselles, 478 millions; Marselles, 478 millions; Marselles, 478 millions; Marselles, 470 millions; Marselles, 470

The Languet Reisforced-Concrete Arch.—What will be the longuet arch in reinforced-noncrete is now being suits at Languets, Bettierdand, on the Chur-Aross Radiway. The arch will have 160 feet rise and a clear length between abuttonite of 330 feet. This will be the languet attructure of its kind in existence, being about two feet longer and 130 feet higher than the Risorgimento Arch over the Tiber at Room, Italy.

Test of Canal Gates at Miraflores.—On August 25th water was turned into the Miraflores looks to test the watertightness of the gries, which proved to be quite satisfactory. By the time this reaches our readers the last of the earth of Jees holding out the waters of the Paolite will be removed, and the tidal waters will extend through the canal to Miraflores. This section of the canal will then be in the completed condition, with the exception of a little finishing up by the drodges.

Even-may of Sterage Battery Railroad Cara.—The Prunsian State Railways, after an experience of many years in the use of storage-battery cars on their system, have found that, without making any radical changes in the standard railroad care, storage-battery propulsion may be applied unacceeduily in respect of both operation and economy. According to the Eleiracia Resize, the cost of operating the 200 cars of this type on these railways works out at only 1.75 cents per horse-power per hour.

To Build Up the Fleating Navy.—We are heartily in sympathy with Scoretary Daniels in his determination to band every effort toward brigging up our many affoat to its proper standard of strength. He is reported as stating that he will recommend to Congress that appropriations be devoted more completely than ever to the construction of battleship destroyers, subhnarine tenders and colliers. In order to compensate for the one battleship programme of the two preceding years the next appropriation should be for four battleships.

Memorial is the Late Sir William White.—We commend to the attention of those who are interested in nearly and nativelled matters the four that a meeting was recently held at the institution of Naval Architects. London, to establish a memorial to the late Sir William White. It was resolved to form a committee representing the naval and merchant services, as well as the engineering profession, in order to carry out the object in view. Promises of financial support will be received by the secretary of the Institution of Naval Architects, 3 Adelphi Terrace, London.

A Fostitinger Reduction-Gear Economy.—The Fost-tinger reduction-gear may be broadly described as a few decideding pump discharging into a water wheel, with regulating vance to determine the relative speed of rotation of the power and the driven shafts. In the celebrated tests made recently at the Vulcan Works. Hamburg, an efficiency of shout 10 per cent was secured. It is now proposed to add about 2 per cent to the officiency by utilizing the heat developed in the water of the reduction gear, for heating the feed water in its passage from the condensor to the buffer.

Steel Bulkheads Confine a Fire.—On the occasion of the last trip of the "Imporator" to New York, detective Insulation caused an authorsak of fire in a provision room in the after part of the ship, which served to prove the value of steel bulkheads in limiting the spread of fire. The watertight bulkheads below and at the waterline should find their counterpart in fire-proof bulkheads above the waterline. Our roaders will be interested to learn that the fire was automatically made known by the issuing of anoke from the Rich Marine Fire Detector on the bridge. This device received the first Scientific American medial for safety.

Chilled Iron Car Wheels the Best.—In a paper cod at the May meeting of the New England Railroad Club, Mr. A. A. Hale showed that, in the development of the freight car from 20,000 to 100,000 pounds capacity, all parts of the car have issen increased in weight, but no part has shown such slight increases as the chilled-iron wheel. Car capacity has increased 400 per cent, the weight of axia 140 per cent, the weight of axia 140 per cent, the wheel has increased only 38 per cent. In the opinion of the author, chilled-iron is the only metal of which whose a are manufactured which will stand up under extremely heavy loads without crushing or flowing.

Marine Diesei Engine Development.—Advocates of the application of the Diesel engine to large vessels, says Dr. Lt. Himshberg, in Poser, are endaworing to surb to a dagree the over-enthusiasm of radical supporters, who are prone to claim too much for this type of engine on account of the success of such vessels as the "Silandia". The short experience of arc batand with large oil engines on heard ships (while unineatly said short experience and owners), cashes specialistic oil difficult as yet; and the writer consistent that the prediction of street of the state of the sta

#### Science

General Michael Rykatchew, the veteran director of the Russian Meteorological Service, has just announced his retirement. He has been connected with the Central Physical Observatory (the headquarters of official meteorology in Russis) for 46 years.

Moving Pictures in Medicine.—Press reports tell of the invention of one Dr. Rosenthal, which was submitted for inspectuon at a meeting of the Physoutherapeuties Congress at Berlin last spring, which rendered it possible to make cinematographic views of internal organs to provide an illustration of the workings thereof and to facilitate the localizing of diseases. The invention is said to be an adaptation of the X-ray and is thought by some to promise great things in the way of diagnosis.

The Publications of the U. S. Department of Agriculture represent, in the aggregate, the most voluminous body of literature currently published by any scientific institution in the world. In order to meet the needs of scientific workers who now have difficulty in locating just the material they want in this great mass of publications, plans are on foot to establish an official research journal which will bring together all the results of important original investigations in the Department. Radical changes are also proposed in the plan of publication of the less technical literature of the Department, but the details of the changes have not yet been made public.

Ostwald's Assales.—Some twelve years ago Prof. Wilhem Ostwald founded the Annalen der Naturphilosophie, as an organ open for the discussion of those questions of philosophy which have arisen in late years through the very rapid growth of secentific knowledge. Prof. Ostwald himself has taken much interest in the development of questions relating to sociology, or to be quite exact, "Kulturphilosophie," as the German term has it. Our readers may result that one of the fundamental principles upon which tostwald bases he system of "Kulturphilosophie," is that all our doings must finally be aimed at increasing efficiency, or in other words, decreasing wasteful effort. In view of the prominent place which this particular branch of the decided to change the name of Ostwald's Annalen, which henceforth will appear as "Annalen der Naturnal Kulturphilosophie." At the same time Prof. R. Goldecheid has joined Prof. Ostwald upon the editorial staff of the Annalen. The sociological place of the work will be mainly in the hands of Prof. Goldeched.

Dried Yeast.—In the Bulletin of Agricultural Intelligence and Plant Diseases (Roms) Dr. F. Hayduck describes the remarkable development of the dried yeast industry in Germany during the passat produced intelligence of the Grant Development of the produced the second produced the passat produced the second produced produced produced the second produced p

Accology in the Arctic.—The plan of carrying on systematic upper-air observations with kites and balicons at stations surrounding the north point basin, in connection with the similar observations that are no be made by the Amundson and Stefansson polar expeditions, has now reached a definite stage of progress. An international commission has been organized to direct the undertaking, constiting of Gen. Rykstohew (president), Prof. Rergesel (secretary), Capt. Amundson, Capt. Ryder and Prof. Stupert, and a tentative programme has been drawn up. It is expected that stations will be in operation at the following points, and approbably others: Nova Eembla, northeastern Siberia, Spitchergen, northern Norway, Yakutak, Verkhoyansk, Iosland, Greevland (two stations), northern Labrador, Frans Josef Land (Reyer expedition which stated August 10th), northwestern Alaska (to be equabilished by the Carnegie Institution). It is recommended that all observations begin in the summer of 10th, the time of Amundsen's expected departure. Prof. Hergesell announces in this connection that the Germas scientific station in Spitaberges, which is ecompied chiefly with newtological investigations, will be maintained for at least the next three years.

Agricultural Tractor Trials in Germany.—By way of colorating the revolt of Prussis in 1813, the Königsberg Chamber of Agriculture is to hold a big agricultural exhibition with specal trials for monhanical plows operated by internal-combustion engines. The tests are to take place the end of May and the fixer of June and particulture can be obtained from the Königsberger Landwirtschaftskammer.

Maxim Silencer for Gas Engines.—In patent, No. 1,000,425, Hiram Percy Maxim of Hartford, Conn., presents a alencer for gas engines which comprises reversely directed, eccentrically arranged and nested series of wide cylindro-spiral shells formed to provide a series of alternately reversing spiral-which chambers which gradually oxpand radially from the admission end and gradually compand radially from the admission end and gradually contract toward a constructed discharge threat together with co-operating and supporting means which he utilizes in securing the deserved sincing offect.

Motor Trucks in Tripoli.—According to Information which appears in the Milan daily press, the Italian war department has been engaged in a series of very inter-cuting transle with power wagons in the Tripoli region, and these proved such a success that the army is going very largely into the use of power wagons in the near future, it benn desured to change over from here wagons as completely as possible in view of the many advantages aforded by the automobiles.

An automobile Improvement.—It is reported from Paris that the French authorities contemplate the adoption of a law or regulation making it obligatory to provide within an automobile some means whereby the comparate of the var, other than the chauffeur, can bring the ear to a step in case the chauffeur should become unconserous or otherwise disabled from handling the ear. Attention has been espocially called to the necessity of such an improvement by a recent accident in which a ear ran overbrard, when the chauffeur became unconscious, and resulted in the drovining of several children and other passengers of the ear. Doubtless the application of some means to prevent the operation of the safety devices except when absolutely necessary.

Camphor as a Vitalizing Agent. - Alroad, where great pride—and just pride—is taken in the milesge per gale in of fuel that can be entitained, a small band of motorists recently has been experimenting with gum compiner as "dope" for gasoline. Usually, about one ounce of camphor is piaced in five gallous of gasoline and it is stated by those who use the mixture that the operation of their motors is much superior with the camphor in the gasoline than without it. One motorist even goes so far as to claim that he has been able to increase his mileage per galion as much as 20 per cont, though it would seem that the increase cannot be due to the use of the camphor alone. The idea is not new, of course, for Curtiss, at present of acceptainer fame, used it as number of years ago in his racing motorsycles and it is said he sometimes uses it now in his accordance.

Rubber Tires and Automobiles Are Different Goods.—The Court of Appeals of the District of Columbia in Q. & J. Tim Company v. G. J. G. Motor Car Company has hed that rubber tires and automobiles do not constitute goods of the same descriptive properties within the meaning of the trade-mark las. The decision quotes a previous decision of the same Court in which Mr. Justice Robb, speaking for the Court, and "We think two trade-marks may be said to be appropriated to merchandiss of the same descriptive properties in the sease meant by the statute when the general and essential characteristics of the goods are the same. The rule that the goods must be identical would defeat the purpose of the statute and destroy the value of trade-marks. The test is whether there is such a sameness in the distinguishing characteristics of the goods as to be likely to milled the general public. If there is, only one mark should be registered."

Need for Standard Control. - What with new care counturally being hrought out and now models of old care periodically making their appearance, it would seem that it is a bundant come for standardization in the construction of routed units and particularly in the case of the parachitic tiver. At pression, for ozars are the same, and to make it even more difficult for the purchaser of a new model of the same make be already possesses, control methods often are altered radically. The Society of Automobile Engineers has made a laudable attempt to remedy the evil but it has not been altogether successful, probably owing to the fact that manufactures are loth to discard expensive jigs and tools in order to adopt a standard system. Still, a standard control method would be of material banefit to the owner for he would be able to drive his new car without preliminary instruction, regardless of how short the instruction might be, and what is even more to the point, he would be less likely to do the wrong thing, in driving a new car, from force of habit learned with the old one.

Bituminous surface maintained by one oil and three sand treatments annually

# Automobiles and Improved Roads

The Economics of Motor Traffic and of Highway Construction

By Logan Waller Page,

Director of the Office of Public Roads

Concrete construction. A well-built concrete ros nithough expensive, is cheaply maintained.

D'IRING the year 1912 automobiles paul in repeteration and license foce against preparents and license foce against of automobiles. From this country in 1908. In 1911 we exported automobiles to the value of sparts of automobiles. The curresponding flauer for 1912 was \$25,703,900. In 1912 we lead unterly as many automobiles in New York State as \$25,703,900. In 1912 we had userly as many automobiles in New York State as there were in France and Germany combined. The total number of machines upon our highways last year was a round million. There is evidence at every plane of automobilism in the l'inted States. What is the relation of this great movement to our highways.

We have approximately 222,000 miles of improved roads. This milenare includes not only instet-these highways, but a large milesage of grateded and straves natural soil roads. There is therefore the roads are not to the roads are to the result of the roads are not to the roads are not roads are n

We may expect, however, to find that our improved murdant roads are not withstanding the action of the automobile, and this is the case. Since the use of the automobile is increasing at an accelerated rate, and since, wherever a road is improved, it tends to draw increased traffic, we must avoid in the future the construction of water bound mecodem surfaces where heavy motor travel occurs. There are many places where such roads may be built with economy and confidence as to their service, but in the more deusely populated areas this is not true. The construction of bifurninous-bound mecodem surfaces were not such construction of bifurninous-bound mecodem country since 1966 is due almost entirely to the reaction of the automobile groun the old standard water-bound mecodem surfaces.

There has been an increase in the cost of highway construction, and repuir and maintenance. It does not follow, however, that this increase of highway costs in general is a relative increase jer unit of travel. The traffic over our highways in motor vehicles is in general as suttrey new and added liess of travel. Only in the last wo or these years now as demonstrated in the last wo or they went an are actionidate trucks ascum to replace horse-drawn vehicles for commercial purposes on the

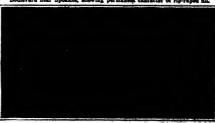

Traffic on clay gravel road (natural soil) near Fredericksburg, Virginia.

Boulevard near Spokane, showing permanent character of rip-raped fill.

Laying bituminous concrete, Hillaide Avenies, Januises, Ser Yes

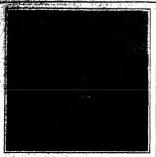

country roads. All hashing, until very recentily, has been done by borne-drawn vehicles. The pleasure vehicle drawn by horses has almost entirely disappeared in most sections of the country, and the automobile has not only replaced it numerically, but has multiplied the number of pleasure vehicles many times. Our insproved roads at present are sustaining, therefore, an amount of travel several times as great as they were ten years ago. The cost of our highways per unit of travel persons.

#### The High Cost of Waterbound Macadam Road.

We have not been building improved highways in this country very long. Before 1983, there was no systematic highway improvement. Not until recently have we been able to determine the cost over a period of years in this country of any of the standard types of roads. The water-bound macadam road was a more expensive road than was generally admitted. It was not customary to add the annual cost of periodic resurrishing to the annual cost of periodic resurrishing to the annual ministenance figures. When that is doub, it is found that the water-bound macadam road, 15 feet wide, costs appreximately \$500 per mile per year, or between five and six cents per square yard. The substitution of bituminous bound macadam aurfaces for water-bound surfaces, has increased the first cost of construction from 20 to 40 cents per square yard. It has apparently increased the cost of annual maintenance and, at present, we cannot say to what extent the annual cost of periodic resurfacing will be affected by bituminous construction. There are, however, a great many instances on record which indicate that the total up-keep of bituminous macadam roads will covered \$500 per mile per year, or

Neoro which induces that the tone one speece of bitminous macadam roads will exceed \$600 per year in the long ran. As we pease in review the various standard types of improved highway surfaces, we see that the cost of their maintenance and repair tends to increase with the cost of fart construction. This law, however, does not apparently hold for the most expensive roads such as well-built concrete, and brick roads, or bituminous with concrete foundation, the questions that is rapidly taking shape in the minds of highway employers in the minds of highway employers in the cost of annual repair and maintenance for a given period of years. Shall we greatly increase the cost of our road surfaces and avoid high annual charges for regarity and maintenance.

tonance During the sonson just closed, the United States Office of Public Roads has built a number of sections of experimental road at Chevy Chase, Maryland. These sections are of the highest types of road construction new favorus to highway send-neers. They include two sections where the product of the control of the c

Basschburg's apparatus to study a child's visual learning. This apparatus provides for a rhythmic successive learning of visual stimuli.

# Efficiency in Learning

A Practical Result of Experimental Pedagogy

By Dr. P. R. Radosavljevich New York University

Dynamometer and aesthesiometer by hich is studied a child's strength an after a period of mental or physical learning.

THE best way to show the dimensions and force of ental Pedagogy is to present its practical results. Like other great movements, experimental padagogy has overflowed the traditional channels of academic work and has become a new popular force. Its watchwords are: "Hydrone of Tecchiss" and "Boosnomy of Learning." ideas that the newer pedagogues are trying to attain with the least expenditure of gagace are trying to attain with the least expenditure of energy. In order that they may be attained the teacher (1) must be at home in his or her own school branch, (2) must know and practise the best way to present school material in the classroom, and (3) must show the pupils how to study most economically.

Saving the Energy of the Teacher and Pupil. Let us suppose that the first two conditions are ful filled. According to the ideals of the old pedagogy such

not satisfied with that klone. Experimental pedagogy asks the maximum from teachers, i. e., the most eco-homicsi way of learning or acquiring a school material explained and understood. Let me illustrate that by an actual experimental case.

A 8-year-old boy of average intelligence was asked, after certain preliminaries, to learn a poem with four after certain preliminaries, to learn a poem with four stances of six lines each, with the instruction to memorite such parts as quickly as possible, and to read aloud and recite aloud until enabled to execute one erroriess technicion. The experimenter, who had copies of the poem, designated the part which the child read by a vectical line on the right. So, for example, if he read four fixes twice, two vertical lines were drawn on the right; if next he reads two lines, a third vectical line of a largeth squal to the space occupied by two lines wis drawn. If we represent the lines of the poem by longituding the state of the poem by longituding these theorems in faiths t.

The latest the second of the poem of the poem by longituding these through the poem by longituding these through the poem by longituding the second in faiths t.

the parts already learned by going back occasionally e learning later parts (either to avoid them or in order to associate the parts with one another), that the first lines were repeated oftener than the last ones. and that the difficult parts (or words) were learned by means of special repetitions. This is the old, the usual, the uncontrolled, the unconomical method of learning, a memorizing left to accidental success and planless efforts. This is called "the part method,"

phaless efforts. This is caused "one pur meason," piece-meal," or "cumulative" or "practional" learning.

A week later the same boy was asked to learn a similar poem (both in quantity and quality) with the instruction to repeat it always from the beginning to the end until it was learned. The following graphic tation (Table 11.) shows the results

Here the same child needed only 15 repetitions, and his reproduction was more uniformly associated; he avoided too many or too few repetitions upon respec-tively easy or particularly difficult lines or verses. This method of learning is called "the whole method" or "the

method of tearning in caused "the booled method" or "the complete method."

Both the placement and complete tearning agree only in the fact that the child commits to memory in one stitled, i. e., a poem is learned in one day without interruption of time intervals between repetitions

A week still later the same pupil learned a similar poem, but in this case the child repeated the poem—by poea, but in this case the child repeated the poem—by the whole method—only once a day. The time of day was 9 A. M., the same as in the previous two experi-ments. The results are shown in Table III. Compared with the previous two methods this plan

Compared with the previous two methods this plan of learning proved still more economical; not) 8 repetitions were required. This method may be called distribution whose method. Its value has been demonstrated experimentally by Zoot, Menuman, Ebiblighaus, Magnoff, G. E. Müller, Pentschew, etc Zoot found that 2 repetitions on 12 successive days were better than 8 repetitions on 3 successive days. That this method is most economical and most natural is also proven by the fact that the Servian gustars (national proven by the ract that the servian passage (national folk singers) learn a national cpic or lyric song (sometimes 500 to 1.000 lines long) by distributive whole method only, i. e., by listening to the recitation of another yester. This method of learning is used also by the Greeks in committing to memory long Homeric

To ascertain the value of these three methods, the suits are tested after a certain time interval. I asked

A Salar Salar

same child to relears the same three poems after 28 days. All these experiments were carried out in Meumann's laboratory at Zürich. The results are shown

	Pirst Laurning	R	olograing		
Mesteri '	Number of repe- titions	After an interval of	Number repeti tions to relearn	Absolute	
Part method Whole method Distributive Whole method	1	Days 28 28 28	10 6	16	38 4 60 6 77 8

From this table it is seen that the percentage of saving in relearning is greatest in the distributive who method (77.8 per cent), less in the whole method (60 per cent), and least in the part method (384 per cent). These results were verilled also in a more homo-geneous material for learning, in so-called nonsonso syllables, e. g., lei, rit, fos, zam, ped, des, etc. These

syllables provide little attraction to the memory, cause they are almost devoid of associations, I. e., they neutral material in learning experiments. In mem origing such syllables my 28 subjects read them in a oraning such solutions of 2 superior variation in a regular succession, by means of a special apparatus. (see accompanying flustration). Of course, the words whose mountage are unknown, are memorized and rejeated with more or less difficulty for all manner of reasons, but the relative values of these three methods is the same as in the case of poe

#### The influence of Age.

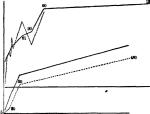

Age is another such secondary factor that the above mentioned boy needed 63 repetitions to commit to memory (by the whole method) a series of 12 nonsense syllables, and an adult (a university stu-dent, 22 years old) needed for the same series 13 repetitions only Consequently the popular opinion that children memorize more quickly than adults is erroncons. The child's superiority consists only in retentiveness, i. e., a child needs less repetitions to relearn material once memorized, but the number of repetitions required for learning the first time is greater for young children. In other words, adults surpassed children only when the work was prolonged, but children needed less repetitions in relearning

Another secondary factor is the time clapsed between first learning and relearning i found that the time saved in relearning decreased with age for all but the

The state of the s

5- and 20-minute intervals, as it is indicated in the fal-

	Per cent	of Forgett	ing for 97 sub	jects.
Relearning after	18 Adu	ilta	11 Child	iren
	Nomense Bylishies	Poems	Nonsense Syllables	Poema
6 minutes 20 minutes 1 bour 8 hours 1 day 2 days 6 days 6 days 7 days 7 days 14 days 21 days 30 days 7 days 120 days 6 days 7 days 120 days 120 days 120 days 120 days	2.5 11 4 20 3 52 0 31 1 39 1 50 7 50 7 50 0 97 2	0 0 3 9 21 7 41 9 3 88 2 43 5 48 5 5 48 76 1 76 0 52 4 76 1	8 H 14 6 22 7 37 0 28 3 31 0 42 4 46 1 49 5 66 2 94 3	1 7 5 5 17.9 35 3 20 7 28 2 

The curves below show forgetfulness during the day (after 6, 20 10) and 480 minutes; the curves shows show the forgetfulness after 1, 2 3, 4, 5, 6, 7, 14, 21, 30, 16, and 120 days In both cases the broken likes represent forgetfulness for peetry, and the continuous lines show forgetfulness for peetry, and the continuous lines show for settliness for mentinginess words. The children led association strength somewhal faster than the adults, the association strength at the end of one day was greater than at the end of 1 hours or at the end of 2 days.

Another factor is the child's general intelligence. bright child, on the whole, needs less repetitions than a dull one, but the lutter retains better.

The mental type of the learner counts also Although all my subjects experimented upon were of mixed mental (or ideational, monory) type, it was a great held to each to follow b a or her own predominant type of memory with which few seem to be familiar

#### How Rhythm Affects Memorizing.

Rhythm is one very important element in all kinds of learning; it forms an extra association between the varied stress it brings and the syllables so stress All learners are inclined to use rhythm and tempo, tre ing many at first and focusing later to a few; distinct injury is caused to the memory of anything once ac quired when it is relearned in a different rhythm. Of course the rhythm suitable to what is to be learned should be adhered to strictly. In learning lines of unconnected words and parts of a poem, Ebbinghaus found that a rate of 200 lambics per minute or 0.3 second for each measure is the most advantageous; and in learning the same lines 24 hours later, he also found that those lines had been better retained which originally were learned with greater speed. Meumanu and Pentschew found that, in general, for adults halfaloud learning (of nonsense syliables) is more favor children silent learning or that pressed voice

Practice has a great effect. I found that the num ber of repetitions necessary both to learn and to relearn diminishes with time, but the growth of practice is far greater in learning than in relearning. I found that a special practice in memorization improves mem-orization in general. This is also shown by the experiments of Meumann and Ebbert. I also found that there are distinct slow and fast types of learning, although the former may by practice approach to some extent the latter, so that the difference may be due to practice

#### The Will to Learn.

Of course in every method of learning the will to learn is essential. A striking instance for that is shown in my experiments. I gave a foreigner who understood no German a series of nonsense syllables. This subject not understanding the directions, read the syllables 46 times without committing to memory. When I asked him if he could repeat the series he exclaimed: "What i Am I to learn them off?" Then with 6 repetitions he

Meumann and Mayer tested the ability of school children to work alone or in company with others, and found, in general, that the work of pupils in groups (in

the class room) is superior to their work as individuals (working shape in the class room). Schmidt generally speaking, that the quality of the hom is interior to the school work.

Many have tried to show that learning is influence by the sex, correlational, diurnal, weekly, monthly, as asonai factors. But there are many crudities of seasonal factors. Int there are many crucicles of method and trivialities in the way of such results, because many people are attempting kinds of work in various fields for which they are totally incompetent. Of course every great movement floats many faddlsts. who are really irrelevant in the problem of economy of learning, this great postulate in modern school edu-

#### Emergency Repairs to a Destroyer

#### By J. F. Hellweg, Lieutenant Commander U. S. N.

DURING the last winter's maneuvers of the Atlantic Fleet off Quantanamo Bay, Cuba, two of the destroyers collided about twenty-five miles off shore. The "Burrows'" low was twisted to port about eight; degrees and was budly crushed, as shown in one of the front-page photographs

This injury, while not endangering the safety of the ship, effectively prevented the "Burrows" taking any further part in the fleet maneuvers. Had such an ut occurred during wartime, the ship could not have been operated and, had she been chased, she could not have escaped, as her speed was practically killed. A destroyer in such condition would sadly haudicap and the fleet, since she would require protection and could only make about six knots

White returning to Guantanamo Bay, plans were out-lined for repairing the bow and were submitted to the Flotilia Communder shortly after our arrival in p

The next morning the ship was placed alongside the dock on one of the numerous cays in Guantanamo Bay, all weights, including auchors, chains, ammunition, fuel oil, fresh water, stores, etc., were shifted aft, and the cutting out of the rivers on the stem was commence

We knew that the ship's keel was broken short off about two feet abaft of the scarf of the keel and stem; but the ship's weights were not sufficient to raise the bow so that the break could be reached. A large and was therefore lauded on the stern to lift the bow. The ship was then run inshore till the forefoot took on the cradle of a small marine railway used for repairing launches, small tugs and barges, the ship being steadled by large barges on both sides. By this means, w was placed in water about four feet deep at low tide.

To permit the use of air tools a small air this was phed from the ship's air compre was rigged with three ontiets. Air tools were borrowed from the fleet, and the men were arranged in to push the work as rapidly as possible.

Scaffolding was built around the bow with targetruft material, and the ship's searchight was dismounted, taken on the beach and mounted so that the light

could be thrown on the work.

Men from the U.S. S. "Dixle" and the U.S. S. "Monaghan" helped the crew of the "Burrows" through-out the repairs. As the keel had been broken short off out the repairs. As the seen man been conven short on about two feet about the scarf of the stem, the latter was all clear for removal as soon as the rivels had been cut out of the side plating. The stem was dropped oard and hauled up on the beach, where it was straightened. Owing to the lack of facilities, the stem had to be heated and straightened in spots, the twists being gradually worked out of the stem. This straightening, under the existing circumstance ample of what an American bluelacket can do with little or no facilities or tools at hand.

The port plating was so badly twisted and torn that

none could be saved. The starboard plating was heated by a large blow torch and incled back into place by tackles. Some of the upper plating on this side had to be renewed. The ship's frames were so 'adly crushed that they were thrown away.

After the straightened stem was swung into place,

it projected about eighteen inches above the lev the deck, this being due to the latter's having been pulled down at a sharp angle when the stem was twisted and the keel broken

et and the Kee broases.

It was impossible, at first, to raise the deck; but, by sitting the huiged plating close up to the deck on both bows, the forecastle deck was jacked up into place and the stem bolted in position. The starboard plating was riveted in place and the port plating was then built up by sections.

The broken parts of the keel were chipped off flush

butted together, and then secured by a shoe of %inch botter tron and eight through boils, as shown in sketch. The discarded ship's frames were replaced by oak stringers and breast-houls. These were put in position, wedged apart anug against the skin of the si and secured in place with through bolts as shown in the sketch. Cement was poured in through the filling

ak stringers and breast hooks were alternated in building up the bow.

2.33

huliding up the bow.

In ninety-one working being the flow mar bonn and trivily cut off and rebuilt. The ship was intent to Hospital Cay at 10 A. M., March 7th, 1913, and backed preself off at 1 P. M. March 14th, 1918, ready to take

hereset on at 1 t. As. mercus area, acas, respect to new her place in the fleet and ray at any speed. Inquiries have been made, and this appears to be the first time in our Navy that such a job was ever undertaken by a ship's company. The crew averaged thirteen hours a day in repairing the bow, some of the men working in water halfway between their water and shoulders for hours at a time. With the assistance of the searchlight, the work was pushed till a late hour every night, when it was possible, and the sn and cheeriniues of the men was such as to make one proud of the American bluejacket.

During the maneuvers the day following the completion of repairs, the "Burrows" ran at high spe a good sea with no trouble. A month later she entered the quarterly full-speed race and maintained her previous position as the fast boat.

The American public never hears how the young Americans who serve their country in the Navy rise to any situation, and perform unexpected duties quietly and efficiently without thanks or commendation—duties which, in wartime, would attract the attention of ever e United States and win for them the thanks of their fellow countrymen

#### A Railway in Iceland

A T present methods of travel in Iceland are of the most primitive description; a few carriage roads exist in the south, with bridges over the rivers, but generally throughout the island journeys are made on increciació, over bridie-paths or no paths at all, and streams have to be forded. A few years ago the Althing (national assembly) voted funds for surveying the route of a railway from the capital, Reykjavik, in an easterly direction through a comparatively populous and thriving region, and one much frequented by tourbets. Plans are now complete for this line, which will run from the capital over the Thingvalla plats to the Offusa bridge, a distance of about fifty-sight miles. The estimated cost of construction is \$1,000,000. Ultimately it is proposed to extend the line to Thorsian. with two branches from that point, one leading to the geysers, and the other to Oerbak. The railway project keysers, and the other to occusion. The Fairway project has led to ambitious plans of drainage and irrigation along the proposed route, opening up extensive pasture lands and enlarging the already important dairy industry of the country. To the tourist the railway will offer an agreeable substitute for the present tedious ourney by pony to the geysers, Mount Hecia, and other

#### Hawker's Failure to Win the Daily Mail Prize

HARRY A. HAWKER, the solitary entrant for the Duily Mail prize of \$25,000, offered for a flight in A nutly Mail prize of \$25,000, offered for a flight in a hydronerophuse around the coast of Eugland and Sectional, came to grief 15 miles north of Dublin on August 27th. He had then covered 1,043 miles of the total of 1,550. At Obstrone of the floats of the mechine had to be repaired. Engine trouble brought Hawker down of Arghibaltica. After crowding the sea to Larne, further adjustments of the engine consumed an hour and a built. He accorded neaths of the contract the contract of the season of the contract of the season of the and a half. He ascended again and flew stead two hours and a quarter, when, curiously enough, the siliping of his rubber-soled boot caused him to lose siliping of his rubber-soled boot caused him to lose control of his machine, so that he plunged into the water from a height of fifty feet, near the shore. Hawker was only bruised, but his mechanic's arm was broken. The machine was hopelessly wrecked, It is said that the Daily Mail will present £1,000 to Hawker in recognition of his brave attempt

#### The Current Supplement

In this week's Issue of our Superlement Prof. E. L. Schwarz contributes an article on new types of volcances in Iceland.—The production of synthetic tandard and many house to appet the production of synthetic tandard and ning is reported, and may prove of considerable interest to the leather industry.—E. J. D. Coxe gives us an illustrated description of Open Air Coal Mining as carnuarrated description of Open Air Cool Mining as car-ried out in Pennyiyania.—W. A. Nicholson contributes an article on bird calling, which is illustrated with pictures of different forms of whates used to imitate birdcalls—The second installment of Lieutenant Col-onic Kuluis article "Some Aspects of the Subject of Transportation" deals with traffic by water.—John C. Parker wittes on the industration er writes on the industrial use of synchrone tors by central stations.--Prof. E. E. Barnard puts on record for future observers the present appearance of some temporary stars.—Charles Kassel contributes in article on Heredity and Gentus.—The views, ofttimes article on Herenty and Gentus.—The views, outcome qualit, held by prominent thinkers of the past and present regarding the seat of the soul, are reviewed by Dr. D. F. Harris.—An important discussion on life-sources of motor fuel held at the nightist flower Trans-portation Conference, is rejected in this issue. 

## Patents and Modern Industrial Conditions

#### The Stimulus of Patent Protection

By Frederick P. Fish

I REPRESENCE has demonstrated that so form of re-levant so fitted the enthancement, was so productive of advantage to the community and was actended by so fav disadvantagies as the grant to an inventor of a monopoly of his development on the limited time. While many other forms of several have been suggested (such suggestions were inside at the convention which adopted our maweek make at the convenion warm samped our in-tional constitution), they have nowhere seen adopted as past of the machinery of society. Everywhere some form of exclusive control for a limited time has been recognised as the best way of dealing with the matter.

The encouragement of patent protection does not alone stimulate the inventor to intellectual effort; it excites to strenuous effort a long line of intermediaries capitalists, investors, husiness administrators, diceneces and users who work with or under the patent and whose eration is vitally necessary that the invention may not be confined to a paper description, but may

actually get into use.

After all this line of public servants has been rewarded, the uitimate consumers get their advantage from the invention, even during the term of the patent, in the form of less cost, added facilities, increased comfort and greater convenience; and their gain, while the patent is in force, is undoubtedly in almost every case infinitely greater than that of those who profit directly from working under the patent. Of course, when the patent expires the invention is free to all.

Until 1888 Switzerland had no patent law. It was argued that, situated as Switzerland was, in the heart of the industrial world, with a docile and intelligent population, trained by an admirable system of educa-tion, and with the great advantages by way of watertion, and with the great advantages by way of water-power which the country possessed, it could progress more rapidly if its citizens were all free to appropriate for the national industries the ideas, patented or un-patented, of the rest of the world, without the grant of any monopoly to individuals in Switzerland itself. This policy was, however, found to be short-sighted and illadvised. The Swiss were not encouraged to invent. More than that, they were not encouraged to adopt and introduce inventions. They did not develop the desire to improve. Because they had no patent system, their industries did not advance satisfactorily.

Under the stress of the necessity that inventions should be fostered in the community, if industrial progress in competition with that in patent-granting c tries was to be secured, a patent law was adopted in 1888. Since then there have been over fifty thousand patents issued in Switzerland and her industrial pro

gress has been marked.

Holland in 1863, before the extraordinary expansion of the latter part of the last century had even begun sholished her patent law, undoubtedly influenced by the hope that her situation was such as to make it more for interest to take freely the inventions made any where outside of her own boundaries than to attempt to develop inventions and the inventive habit among her own people. It is significant, however, that she has, ufter trying the experiment for more than a generation, recognized its futility and has now again established a patent system.

Inventors Helpless Without Patents.

Nowhere can it be worth while to invent, unless there

is opportunity for utilizing inventions if made every citizen were an Edison, it would not profit him to work out new ideas on paper or in a laboratory un-less the conditions were such that they could be intro duced into use with the chance of a proper return. inventor therefore is helpless unless he has something to offer the manufacturer or the capitalist that will justify the latter in paying for rights to the invention. An adequate patent system gives to the inventor, who as a rule never could himself do anything with his inventon, something that is taughbe and of value, which he can transfer, in whole or in part, to the business enterprises which alone can make the inventors. tion of value to the community. Inventors, and business men who develop inventions and introduce them to ness men who develop inventions and introduce them to the service of man, to exactly the same degree and for the same rasson are stimulated by the protection affort-ed by a patent, to efforts which they would never other-wise make. Each class would be helpiese without the other. It is only when both are encouraged and pro-tected, as they are by the grant of a patent, that the rectors, as two are yet res grants or, a protest, can be promptes of the merhal arts in prometed. Even if the invention master is mad demand, there is frequently the opportunity and command, there is frequently the opportunity and command or the expenditure of a vac-niture of the part of these who are introducing it into me. Account of the part of these who are introducing it into me.

always there is the chance of utter failure.

Under these circumstances, neither in Switzerland or Holland, nor elsewhere, could capital be expected to take up and push new inventions under condi where, if success were achieved, the full benefit of the invention would necessarily be immediately shared by all competitors.

ct, competitors would have a great advantage over the manufacturer or the capitalist who bore the brunt of the preliminary development. They would have borne no part of his burdens and expense, but would, without cost, adopt from him the perfected thing to which he had devoted so much energy and in which he had made such a large investment. They would reap where he had sown Under such conditions even the most brilliant inventor council get the help which he must have.

The effect of a sound patent system is to overcome these obstacles to the development of inventions, to succurage men to invent who would otherwise have very little reason for inventing, and to attract business men to the arduous task of perfecting and introducing inventions when otherwise they would be in-clined to leave them severely alone.

Superiority of American Patent System.

The standards and rules imposed by foreign paten laws as to working inventions, and as to the grant of ory licenses, are and must be purely arbitrary. Even if wrong in principle they may operate reason inventions But in so far us one operate they are fatally destructive in many cases and no man who is inclined to invent or to proon can be sure that any particular invention will not be one of a class that is necessarily ren-dered unprofitable because the law falls to give him a free field for effort during the term of the patent.

ter a somewhat careful investigation of the situa tion in foreign countries, I am satisfied that the so-called es and computatory license clauses of for eign patent laws are hostile to the real public interest and that they operate greatly to the discouragement of invention and thereby distinctly stand in the way of the sound development of the useful arts. I believe that the simple provision of the United States patent iaw that after the grant of his patent the patent owner shall control the invention absolutely for a short but definite term, having no more payments to make and no fear of interference from competitors, during the term, gives to our people a far greater stimulus to invention than does the law of any other country. The result is that to-day there are not only a very

large number of men struggling with inventive prob-lems or who are on the lookout for the opportunity to invent, but the effort has been systematized to a large extent in accordance with the scientistic principles upon which modern business is carried on. With the large enterprises of the country, inves much a part of the systematic organization of the business as manufacturing or selling. Intelligent men are employed to determine the problems of the business and to find in what direction improvements should be made that there may be extension into new fields. In creased production, greater economy, or an improved product. Highly trained engineers and inventors attack the problems as they are presented and work then out in well-equipped laboratories where not only tech nical skill, but thorough scientific investigation, ried on almost regardless of expense, are appli their solution. Meantime, as always, individuals, even ost humble, are inventing or hoping to h They know that nothing is more likely to advance them I wealth and comfort than an invention, the oppor-tunity for which is wide-open before them, reward in proportion to the merit of what they may accomplish, being almost more certain than in any other field of human endeavor.

Patent System Imperative Under Present Unstable

Conditions.

Continued and incressant industrial improvement is essential to our well-being. In the practical arts there is no such thing as a stable condition that can be relied upon as permanently satisfactory. Unflagging in-

iled upon as permanently setfashedory. Unflagging lineution is required at every stage of progress.

Up to a recent time our sétuation in all respects has been such as to pruncte Sachastrial Gevelopeent. We have had as a background for it an ecommons amount of free land which was open to cultivation. This has now been practically arthousted. This circumstance affects our industrial sétuation disadvantapound; but it had to come. We must use every weapon to neutralise the loss of this asset.

The prevailing popular sentiment of to-day and the new laws and new interpretation of old laws based upon that sentiment are such as to require a definite readjustment of business and of business methods in all their relations. But the process of readjustment will surely be one of shock to our industries. They will endure, even if they could never have grown to their present proportions had the ideas of to-day prevalled fifty years ugo. It is, however, clearly a time in which we should hold on to any feature of our social organization that is right

Foreign competition is sure to be more serious every ear. To-day, except for the artificial protection of turiff laws, the whole world, because of improvements In transportation facilities due to invention, is in immediate competition. No industry one torive in any country unless that country has peculiar advantages, either matural or acquired, so as to be able to produce at such low cost as to meet the competition of other countries. The natural advantages of the United States are great in some directions, but are by no means controlling as to many of the industries. competition with foreigners we are hampered in many ways. In our cost of production we are embarrased by the high cost of our labor us compared with other countries. We have lu the past more than held our own in International competition, partly because we have surpassed all other countries in shop and business organization, but chiefly because of our superiority as Inventors and in the quick and comprehensive adop-tion of inventions. If the process of continuous im-provement is checked, we shall lose this advantage and there will be no alternative except the destruction of some or many of our most important industries or a reduction in the wages and standard of living of our workmen.

The opportunity for improvement nts based upon luven tion is in many branches of industry growing less There is no longer room for the striking advances in agricultural machinery, muchinery for making fabrics and shoes, electrical and other power apparatus, machinery employed in the production and working of wood and metals and in other great departments of ludustry that there was a few years ago. It may almost be said that many of the arts are already developed almost to the point of saturation. It is not so easy as it was to find out how they can be improved There should be every possible and to improve them incentive to seek out and to develop an incessor series of minor improvements which may in the aggrega ford great possibilities of advancement. The latter are of a kind that especially requires encouragement, for they do not ground appeal to the imagination and the direct returns from anyone of them are not likely to be large. They are not often developed as the re-sult of a lappy thought. Close and careful study and utific effort carried on persistently, systematic and at great expense is generally required for them. Agriculture and the production of food products may be revolutionized during the coming century by chemical inventions. In other fields there is room for many great and important improvements, which cannot be realized unless our putent system affords the requisite encouragement

More than ever, when there are causes at work which depress entitusiasm and indi back development.

The Oldfield Bill that has been reported by the Committee on Patents to the House of Representatives at Washington is a most serious attack mean our patent

Any provision in the law preventing the imposition of conditions as part of a sale or license of a intented article or of the contract authorizing its manufacture or use, or any requirement that would impose a penalty if the invention was not manufactured, and particularly any requirement by which under any circumstances a license to use the invention could have been acquired for the asking by a person or corporation to whom the patent owner did not wish to grant a license would undonlitedly have checked invention and the develop ment of inventions to a marked degree. The testi-mony before the Oldfild Committee of those familiar with the subject is practically unanimous on this point And yet it is just such an inroad upon the established law of the land that characterizes the Oldfield Rill

The community as a whole, requires for its prospe ity an adequate patent system. I believe that ours is adequate, that it would be a national if it were weakened as proposed by the Oldfield Bli.—
Address delivered September 2nd, 1913, before the

# St. Lawrence Ship Channel Improvements

Constructing a 35-foot Channel Between Montreal and Quebec

By Harry Chapin Plummer

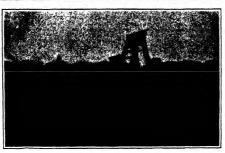

Stone lifter raising boulders at Cape Charles.

WHEN the season of navigation on W the St. Lawrence River closed last tween the Traverse, at the eastern end of tween the Traverse, at the emercia and of the Isle d'Orlents, below Quebec, and Montreul, a contracted distance of 220 miles, was half completed, at a total cost of close upon \$15,000,000. As showing the determination with which the great task is being prosecuted by the Canadian Ministry of Murine and Fisheries, it need only be cited that, having accomplished the opening of a 30-foot channel for 60 60 statute miles, of a total mileage of 63 35 between Montreni and Cap à la Roche, and the deepening of the Beauleu and St. Thomas channels, below Quebec, to a depth of 30 feet at extreme low tide, work being rushed upon a 35-foot channel, also between Montreal and Quebec, u distance of 6.97 miles of which is now completed Inkewise, a good start has been effected upon the north channel below Quebec, which it has been decided to deepen to 85 feet at extreme low tide. The south channel below Quebec has already been deepened to 30 feet and opened to navigation. From 1851, when the first real attempts were begun upon the improvement, to March 31 of the present year, the sum of \$14,524,555.51 was expended and the num-ber of cubic yards dredged totaled 78,-

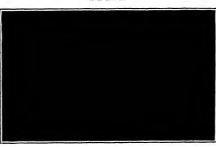

It is tigured that the average load-line of fifty modern vessels is more than thirty feet, and one authority holds that there are only two, or at most three, ports in the world accessible to them. One of these, of course, is New York. The situation of the St Lawrence ports of Montreal, Quebec, and Three Rivers is regarded by the Cauadian authorities as decidedly advantageous, even though the thirty fect may ut no distant time be deemed medlocre. The new improvedeemed medlocre. The new improve-ment, doing away with the probability of delay and accident to ocean shipping, mu greatly advance the position of the thre ports, and further improvements to the St. Lawrence River, to give any reason able depth by dredging, must, as a result of the work now progressing, prove to be not only feasible, but obtainable at much smaller cost than for many rival ports, and it will require virtually a nominal cost for maintenance. At the present time a fine channel of thirty feet at extreme low water, has been accomplished between Montreal and Cap à la Roche, while similar depth is to be had between the latter point and Quebec by taking advantage of the tide. It is estimated that the low-tide channel will be completed us far east as Quebec before the end of another year.

The completed channel has a minimum width, in the straight portions, of 400 feet, and on the curves, of from 500 to 800 feet. The channel does not afford the usual difficulties of canal navigation. There is sufficient water on the banks to minimize induced currents, which, when the cross section of the passing ship is large, in proportion to the cross section of the channel, render safe steering at ordinary speed difficult.

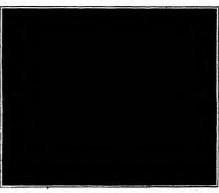

The success of the work is in great measure due to the geographical situa-

Stone lifter with grips capable of bringing up 50-ton boulders from the

Shale rock, dredged without the aid of explosives at Cape Charles.

Section of discharge pipe, showing ball spreaket spring joint between each length of one hundred feet.

tion of the route, to the physical features of the river favorable for improvement, to the determination and public spirit to the determination and public spirit of the business men and industrial corporations of Montreal, and to the recognition by the government of Canada of the national character of the project. Yet an other factor which has contributed to success is that the ship channel elevator dredges employed in the work, which have earned for themselves a wide reputation, have all been designed and built at the government shippard at 1 Sorel, on the south bank of the St. Lawrence, between Montreal and Three litters. Their construction has not been competitive, nor yet cheap; only the beet material has been used, and the most careful workmanship. The dredges are both massive and strong, with a resulting capacity of 6,000,000 yards per a nunum, much of which has been put to test in exceedingly hard material. Because of the fact that the St. Lawrence.

River has its real source in the Great Lakes, it is probable that there is no river in the world so well adapted for improvement. The usual condition of a river presents steep slopes at the source, which erode the banks and transport which erode the banks and transport coarse material. This, as the slope becomes more gradual, decreases, until at the mouth of the stream the water carries in suspension a fine sediment, which deposits to the great detriment of navigation Such has been the geological and geodetic history, for instance, of the Hudson and the Mississippi. In the St. Lawrence the material from most of sources of supply is all deposited in the settling basins, the Great Lakes, and from there to the ocean the bottom of the river is usually hard, so that not only is the water clear, but the bed is permanent, and except for floods during the ice ac-cumulations, the fluctuations in level are gradual, and not excessive.

In the ship channel the material to be excavated varies from soft bine clay, into which a pole may be planted some six or seven feet by hand, to stiff clay, to hardpan as hard as a macedamised road, and to shale rock and large boulders. In one or two localities coarse sand is found, at which points dredging has to some extent to be repeated.

The dredging operations undertaken in the course of the improvement do not either theoretically to practically lower the level of the water. No material is removed; it is merely taken from one piace and deposited in another. So long as the water supply remains the same, the same level may be relied upon. The nature of the material composing the bottom of the river, although in many places very difficult to dredge, is, for the same reason, of such a character that a dredge cut, one made, is substantially permanent.

The currents of the St. Lewrence are, for a river of such size, not only reasonable and regular, but altogether free from the usual dangers to navigation resulting from freshes. The winter season, with its los and anow, is the one great drawback to the St. Lawrence. The successful work accomplished by the ice-breakers during the last two years, however, proven

that the navigation season may be materially length

...

CONTRACTOR OF THE STATE OF THE

rthy feature of the work is that it has be A sistemental Seature of the work is that it has been groupointed in a more or loss swift current and without interruption to the almost constant navigation ratio of the irrer. The dredges are operated, during the season, 125 hours per week, or steadily from midnight on Stunday until noon on Saturday. Only two holidays on Denninch Day and Labor Day—are observed. Stops are made only for had weather, for repairs, for shift-in-increase a phase to aparther or to allow room for are gaded only for not weather, for repairs, for shifting frows one place to another or to allow room for passing craft. Coal is supplied by barges without stopping the work. The steady work at a depth of from \$2 to \$9 feet in very hard material, which is increasing in the resistance as progress is made toward Quebec, and is very taxing on the machinery and equipment. Only a well designed and strongly constructed plant could stand the strain. A dredge capable of re-moving 6,000 yards per day of soft material undergoes a relatively greater strain by the dredging of 1,000
yards of hard-pan, in which boulders are embedded.
A notable increase in the expenditure for operations of late years has been due to the advanced cost of supplies and repairs, wage raises and the greater cost of dredging in hard bottom.

About four hundred men are employed in connection e dredging operations, all of whom are sailors, born and brought up at Soret or at some of the parishes bordering on the river. Most of them have been trained to the service from boyhood. The senior captain of the fleet is credited with the statement the This training of the labor employed has undoubtedly been a factor in the orderly and successful accomplishment of the task, which requires extraordinary care and skill and indomitable patience, the machinery being which necessitates frequent raising and lowering of the steel bar. This is done by the aid of a winch on the scow, the steam for which is obtained from the steamer by means of a flexible steam hose.

"If an obstruction is found while testing, its position is fixed by simultaneous sextant angles taken by two engineers who stand on the bridge of the scow over the suspended roller. These angles are plotted on a chart with a station pointer, so that when the sweeping is finished in one locality, the positions of obstructions, if any, are located and shown on the chart. It is then an easy matter to have these removed by a dredge or stone-lifter, as the case may be.

"The extent of this work may be inferred from the fact that where the channel is 300 feet wide, eight lines are required to be run, and where the channel is wider, it takes from eleven to fifteen lines, and up to

"At the beginning of the season it is usual to run of testing from Montreal to Batiscan through the dredged channel, and afterward the channel is tested more thoroughly The work below Batiscan, in-cluding Cap à la Roche, where the current is strong, and the weather frequently stormy, is usually postpon until about mid-summer Before the work belo Quebec was commenced, one sweeping plant was sufficient, but at present two outfits are kept busy covering the ground required to be tested."

#### Danger from Fire in Steel Shavings

FACTORIES and machine shops which produce large quantities of steel shavings from their lathes may take heed from a lesson recently taught at a large dynamo factory in Plainfield, N. J. In the yard of this factory the steel chips are piled up until there is a sufficient quantity to make a carload.

of motor vehicle operated by steam. The turbine is located under the body of the car. It runs at a normal speed of from 3,000 to 4,000 revolutions per minute, and is geared by means of a terring-hone gear set to the hydrautic transmission which runs at about 600 revolutions per minute.

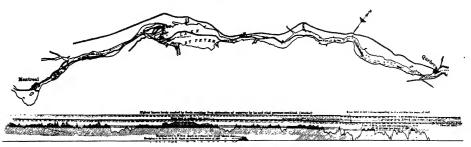

The car is of the single truck type, having only four wheels and all four of these are used for transmitting power. That is, tower is transmitted from the oil pump to the two axles through two oil motors. The turbine will develop more than 25 brake horse-power, which is considered high for this type and size of

Since no oil is introduced in the water which pas to the turidne as steam, it may be used over and over. In order to accomplish this the exhaust steam with be conducted through a series of covered copper pipes conducted through a series of covered copper pipes located on the top of the car. The steam with the con-densed in these pipes and will then return to a reser-voir from whence it may be introduced into the boiler when the water line falls betow normal.

The car witt be tighted by means of Blau gas, which wilt also be emptoyed for vaporizing the fuel under the boiter. In cold weather it is proposed to heat the car by menus of surplus steam from the botter. hydrautic transmission is the same as that used on ne make of molor truck, and is employed in this case in preference to the spur gear speed change.

#### A Giant Aeroplane

THE St. Petersburg correspondent of the Parislan sporting journal Acro telegraphs to his paper that Igor Sikorsky, a student at the technical high school of St. Petersburg, has built what is probably the biggest aeropiane which has thus far anneared Sikorsky's machine is a biplane, the upper surface of which is some

Map and profile showing St. Lawrence ship channel improvements.

forced to the utmost, and passing vessels having constantly to be watched for

As a portion of the channel is finished, it is thoroughly swept with the testing-scow, and if it is proved clear it is immediately opened for navigation. The problem of thoroughly sweeping the channel is one of great importance and considerable difficulty, good weather conditions being an absolute essential. V. F. W. Forneret, the superintending engineer in charge of the project, with headquarters at Ottawa, thus deof the project, with he scribed this feature of the work for the Scientific AMERICAN:

"Although, with the exception of some m Champtain, there is practically no filling in, and although, since the commencement of the ship channe although, since the commencement of the sain channes project no actual boulders have been known to be car-ried into the dredge channel, such conditions being possible, it has been decided that once a year the dredged and shallow channels shall be swept. A twinr and a testing-scow make up a sweeping plant. When this is in operation the bow of the stee er fits into a 'V' shaped groove in the stern of the testing soow, which is securely fastened to the means of strong wire ropes, one on either side, so that the scow is propelled and steered by the steamer. "A steel roller, 40 feet iong by one foot in diameter

a steel roller, so rect long by one root in diameter and weighting about two and a half toos, is suspended under the scow to the required depth, and this sweeps the channel against the current, running a sufficient number of parallel lines to overlap such other, so as to cover the whole ground.

"Formy or smoky weather, due to forest fires, will pt the work, because the shore marks cann interrupt the work because the shure marks cannot or seen for guidance in running the parallel lines. The work has to be stopped also during rough weather. As the work of testing is always done in the channel, a great deal of difficulty and interruption is caused by

neing vessels. . "In think water the dapth is constantly changing.

Sa Grand St. Control of the Control

While a large pile of these chips was waiting for a car to take it away work en set fire to some rub bish near by. This heated the steel and soon there was plainly visible a column of smoke issuing from the pile. A one-inch stream of water was played on the steel for several hours without baving any other than to produce a small but lively volcano cause by steam from the water Then the city fire department was called and after a heavy stream of water was played upon the steel it was thought to be extinguished.

However, the next morning the pile was smoking and faming as vigorously as before and it was necessary to rake the shavings apart before the flames could be subdued. Since all steel chips from this factory are put through a centrifugal oil separator on coming from the machines, oil was not the cause of the spontaneous combustion. The fire was obviously started on account of oxidation taking place faster than the resulting heat ild be conducted away from the steel which was very finely divided, and when the chips became heated from outside source the phenomenon of combustion actu ally took nince

#### Steam Turbine Street Cars for Long Island

A COMPANY has just been organized in New York city to operate an entirely new kind of street car line at Great Neck, L. I. Although the cars will ran on rails and will have every appearance of an ordinary electric car, they will be independent units operating without overhead wires, third rails or central power

The source of locomotion, which is the most interesting feature of this new medium of interurban travel, is a steam turbine supplied with steam from a fiash boiler, the turbine operating a hydraulic speed tran-mission and two oil motors connected with the two xies. The flash botter is located on one side of one lightform and is heated by means of either kerosene or gas oil instead of gasoline as in the ordinary type

what larger than the lower. The span of the biplane is 27 meters, and its total lifting surface is 130 square meters. The weight of the machine is 3,000 The aeropiane has an enormous lifting capacity Besides ten passengers it is designed to carry provisions, fuet for 20 hours and a miscellaneous load of 800 kilogrammes. As might be expected, the power plant is huge Four engines, each of 100 horse-power and each driving a screw propelter are mounted in the machine The fuselage is of wood and is shaped to servation cubin, a spacious pilot hou giass windows for two pliots, a rather large cabin for passengers, stores, tools, a corridor, and finally another cable in which a couch is actualty to be found for

hose who wish to sleep.

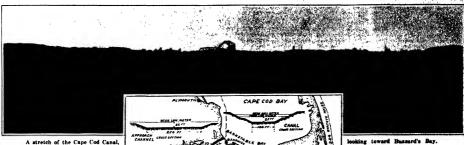

It is said that on August 2 the machine actually ers of 90 kilometers made a flight with seven passengers of 90 kilometers lasting not quite two hours at an attitude of 500 meters, during which the pitots took turns in the pitot house and passengers walked about as if they were in a city apartment Experiments are also said to have been made in cutting out two motors in flight and running the machine with the remaining set of two

the machine with the remaining set of two Naturally these accounts of the machine's perform-ances are received with condderable threshallty in France. To be sure, the acrostovical of Heart Dentiesh de la Meuribe gave a good account of liself in Grance, but French aeropiane designers wonder how equilibrium could be maintained with passengers moving to and fro in specious cabins. Moreover the speed obtained, less than twenty-five mites an hour, seems auspiciously low for sustentiation. Further details will certainly be looked for with much interest.

ard Time in Eritrea.—The Italian colony of Eritrea has just adopted standard time of the meridian of 45 degrees east of Greenwich. Its time will thus be an hour in advance of that in use in Egypt, Portugese East Africa and South Africa.

# The Cape Cod Canal

Saving Seventy Miles of Distance and Three Days of Time in Carrying 25,000,000 Tons of Freight

THE curved arm of Cape Cod with its curious fish-hook termination at Provincedown, which forms such a remark-able feature of the New England coast line, is of glacial origin. It was formed line, is of glacial origin. It was formed by the deposit of boulders and clay brought down from Labrador and Maine, and upon the substratum thus formed, the joint action of the waves and winds of the sea, deposited the sand, which in layers of various thicknesses and in picturesque contours, form such a plea feature in the landscupe of Cupe Cod | Iureature in the image appear to the vide-curving promontory is Cape Cod Bay Where Cape Cod Johns the mainland, at what might be called its shoulder, there is a narrowing down of the width from shore to shore until the distance from Barustable Bay to Buzzard's Bay is only eight Buzzurd's Buy lies between uninland and the southeasterly extension of Cape Cod, which latter gives the same protection to Buzzard's Buy that Cupe Cod gives to the buy named after itself. The narrow stretch joining Cupe Cod to the mainland has a surface elevation of only 20 feet above high water. It is composed mainly of sand with an occusional ad-

Man showing the location of the Cape Cod Canal, and sections of the canal prism

Entrance to the canal from Cape Cod Bay, showing the granite sea wall.

mirture of boulders. A glance at the map will show that the shipping which passes from Botton to New York and southern ports, or eice evras, whether it steams or saits through Long island, at pressout has to pass through Natucket Stoggi and around Cape Cod. Centuries of navigation have shown that the shoule of the Nound and the lee shore of Cape Cod render the route difficult and dangerous, the former because of the frequent fogo obscuring the lightships and lighthouses which are necessary to safe navigation, and the latter because of the dangers of the reefs and the lee shore of Cape Cod, upon which the Atlantic gains beat with great fury, particularly during the winter months.

great fury, particularly oursus to woter months.

The difficulties are aggravated by the fact that the larger proportion of the 25. 000,000 tons of freight which annually uses this outside route is carried in saliing ships and in tows, both of which are particularly exposed to the dangers of navigation above referred to.

In view of these facts, students of the

In view of these facts, students of the problem will see at once that, if the eightmile strip of land between the head of

offic Bay and Barnstable Bay on Cod Bay were igh and a desp-water channel formed, this would not only avoid the dangers of naviga-a referred to, but it would make the trip to en ports wife a very cons ng of time and distance

Several at these and therefore, the first property of Cape Cod Canel will at the nation itself; and we are all familiar the story of Miles Standish, who, an September 2007, whiled his boat up the Squaset River and Delications who is response to an urgent call, had main from New Amsterdam, by way of Buszard's Bay to the resons of the sorely oppressed colony. Later an seminimistan and survey were ordered by the High t of the colony. As far back as 1776, Georg imself recognised the military value of Wantington bimself recognised the military value of this sense; and when she found it impossible to send his known to New Nork by water because of the 8-mile barrier, he said "the interior barrier should be cut in to give greater security to navigation and against

the second. We have before us a chronological history of the Ougs foot Canal movement, which shows how company artist company was formed to cut the canal, several acts of Congress being passed to assist in the enter-Finally, Mr. August Belmont, convinced that and could be made financially profitable,

and moved not a little by the sentimental con-sideration that the canal would be built in the district from which his ancestors had come ecided to finance the undertaking.

The canal is being built at sea level; its length from shore to shore is eight miles; the length from the 80-foot depth in either bay is 13 miles, and the depth throughout the canal for the present is 25 feet. The width of the bottom of the approaches in either bay is 200 feet, and the width of the bottom of the passing places in the caual is 250 and 300 feet A breakwater 3,000 feet in length has been built for the protection of the entrance from Barnay. It should be noted that the turn in the channel has a radius of 7,640 feet ; the canal being practically straight fro to shore

From what we have said of the physical characteristics of the strip of land through which the Cape Cod Canal is being cut, it will readily be understood that the enterprise presents no features of serious difficulty, judged from the engineering standpoint, that cannot be mastered. There are no problems, arising from the unstable conditions of the rock other material through which the canal is exsuch as have added so greatly to the cost of the construction at Panama. The material is such that it will stand upon specified slopes and the banks of the finished canal are such that no crosion or washing away of the banks needs be anticipated. Most of the excavation has been done by means of hydrau-lic dredges. The dredging plant includes two of the largest machines of this type in the world, each of which is removing over 4,000 cubic yards per day from the canal. In one respect only have the estimates of the time of completion been upset, and this delay has e to the unsuspe been due to the unsuspected presence of n deposit of boulders, some of them of very great which have somewhat delayed the and have called for special methods of excava-

The work of the hydraulic dredges has been

supplemented by steam shovels, and the contractors have got such a good grip on the wor August 1st. 1918, there remained only 4,500,000 cubic yards of excavation to be done. During June July of this year, material has been taken out at the rate of 400,000 cubic yards per month, and it is ex-peried that this rate of progress will be increased until altates so e slowing down. If all goes the winter necessitates some slowing down. It all good-diffy well, it is expected that the excession will be completed by July 1st, 1914. The detail disthing un-thight ment be done before the cases is thrown open file concretion will be completed by the following No-members: This diverging of the fone-giles approach in ion may rigidate waters of Sipassiph's Bay is done and fast itsussiversize at the mentals, and in Barnestable Bay following Sichilar about displayed from of greatest is prac-ciable, speciales about displayed from of greatest is prac-

piers is less at Manchester than the 150 feet on the Caps Cod Canal. Furthermore, there are three pensing points where the bottom is 200 feet wide; at the eastern end the width is 300 feet for nearly a mile and the approach in Buzzard's Bay has a width of 250 feet empleted canal will be illuminated through the street-lighting plan, and it will contain the various alds to navigation, these being of the most modern type Navigation will be easy; for it is well understood abroad, where canal navigation is common, that steaming through a lighted and community marrow channel, where the banks are well defined, is safer than steaming from one bright lighthouse to the next through uncertain intervening shoals. This it has been abund-

uncertain intervening shoats. This it has been anumantly and very bitterly proved by our own cosst pilots especially in passing around Pollock Rip.

The opening of the canal will offer an alternative route, the advantages of which over the old outside route are manifest. The average delay per round trip.

The average delay per round trip. per annum for burges in tow and schooners, which now take the Vineyard route, is from three to four days; and this means a loss in money of ten cents per ton on the seven million tons of coal and lumber carried by tow and sailing craft. Although this \$700,000 expense is due in part to the delays at terminals, it is a fact that the barges to-day average only one

M HESA PEAKE 30 BOSTON ΤO BEAUFORT

The system of intra-countal canals, for which Congress is asked to e appropr

round trip per month between the Chesapeake and Massachusetts. The new canal will have sufficient depth to accommodate this traffic and all craft drawing up to 28 feet—a margin which covers all but six of the els at present engaged in the coastwise trade

Regarding the advantages of navigation, we are in-rmed by Commodore J. W. Miller that vessels run out of the southerly rains and mist region as they pass out of the southerly rams and mast region as they pass. New Bedford, and that, as a rule, they carry clear weather and a smooth sea all the way to Boston; while Government statistics show that there is 50 per cent Government statistics show that there is on per cent less fog at Plymouth than at Pollock Rip. Only two northeasters blowing over 40 miles an hour have oc-curred at Sandwich during the past 18 months. Hence the run from the breakwater at the Barnstable Bay entrance to Boston is far safer than skirting the ice off the Cape.

Of the military advantages of the canal it is scarcely necessary to speak. Its present draft of 25 feet will be ample for the smaller cruisers of the navy, for a be ample for me anather crumers of the many, for a large part of the anxillary ships, and for the whole of the torpedo and submarine fleet. Should the United Stakes Government take over the canal and increase the depth to 55 feet, it would then be of sufficient capacity to accommodate the largest bettleships of the mery—in which case it would form an important link

a Branca

in the system of intra-coastal canals which forms the subject of another article appearing on this pag

#### Intra-coastal Canal System for the Atlantic Seaboard

THE present widespread movement in favor of the I construction of a system of intra-constal canals be tween Boslon, Muss., and Beaufort, N. C., has received strong support in the form of a recommendation to Congress, made this month by Brigadier General Bixby. Chief of Engineers of the Army, in favor of the con-struction of the canal by the Federal Government

The arguments in favor of putting through this great ork are based upon the favorable physical conditions along the proposed ronte, the advantages that would be derived by our constwise traffic, and the mival and military value of a chain of interior canals in time of

If a study is made of the several maps which company this article, showing the Atlantic Coast Line from Boston to Besufort, it will be seen at once that its configuration is such as to invite the construction of the interconnecting canals. Cape Cod Buy, Long Island Sound, New York Buy, the Delaware River, and reaches of Chesapeake Bay, Albemarie Sound and Pamileo Sound, already afford several

inudred miles of protected waterway, far re-moved from the const line, which, if connected by canals, would afford a contlunous interior route, protected alike against the shoals and heavy gules of the Atlantic, and against ats by the ships of a hoslile navy

As the result of several years of earnest work on the part of the various commercial in terests, shipping and otherwise, Cangress authorized the army engineers to make surveys and estimates to determine the feasibility of the scheme, considered as an engineer-ing proposition, the prospects of a sufficiently large amount of traffic to warrant the cost of construction, the mayal and military ad vantages of the canal in the event of war, and the best size and type of canal to meet all the conditions, present and future

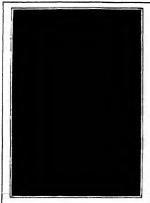

It should be mentioned here that the report of General Blaby concerns only a portion the vast scheme which has been proposed for building a continuous line of canals from Boston, Mass., entirely around the Atlantic and Seniourd to the Rio Grande River. When the Boston-to Beaufort section of the scheme has been completed, and after it has demonstrated its commercial and military value. the serious consideration of the Beaufort to Rio Grande section may come up for consideration in any event, that will necessarily be a matter of the far future

Great credit is to be given to the Atlantic Waterways Association, to whose orgunized efforts was due the provision made by the United States Congress in the River and Harbors Act of March 3rd, 1905, for a survey by the Engineers Corps of the l'ulled State Army, "for the construction of a continuous waterway, inland where practicable, from Boston, Mass to Bennfart, N. C., for the Boston, Mass to Beaufort, N. C., for the with a maximum depth of 25 feet, or such lesser depths along any section as may be found to be sufficient for commercial, navai or military purposes." The present recom-mendations of General Bixby are based on the report of the Special Board of Five Army En-

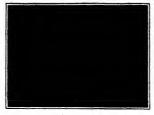

gineers, which, acting under the River and Hartor Act, as mentioned above, was engaged for several years surveylng the route, and presented a report thereon to s last year At that time Congress appropriated funds for the purchase of the Albeniarie and Chesupeake Canal and the commencement of construction of the section from Norfolk to Beaufort

The first stretch of the original proposed 25-foot waterway is that between Boston and Narragansett Hay. Estimates made by the Army Engineers showed that a caust, 18 feet In depth, one Boston and Plymouth would cost \$17,500,000, and an alternative canal, 25 feet in depth, via Trunton and Hinghaus, would cost \$40,000,000. The Engineers also considered the advisability of purchase by the United States of the canal which is being constructed by private capital nt Cape Cod. Commenting last year on the report of the Special Board, the chief engineer agreed with its finding that at the present time there appears to be no commercial necessity sufficient to justify the construction of the canal over either of these inland routes. He considered that after the other section of the intraconstal waterways has been constructed, and the measure of relief to commerce to be afforded by the Cape Cod ship canal has been demonstrated, the question of

Normal condition of sensitive plant before being chloroformed.

When the saturated cotton wool is in position the glass shade is placed over the plant, and the whole is imbedded in hay.

# Can a Plant Feel Pain?

By S. Leonard Bastin

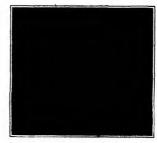

Same specimen after chloreforming shows no sign of feeling a flame.

I T is now generally recognized that there is no essential difference between the evidences of life in the plant and in the animal; there has never yet been any satisfactory chemical distinction which clearly selectrize the protophan of the two types. One can offer no reason why the vital matter in the plant should not be camble of performing that which it is seen to accomplish in the animal. Small wonder then the Dr. Francis barvin and others should discuss the question of plant consciousness and seek for signs of memory in the vegetable being. Certainly the so-called "sleep movements" in the bean, in connection with which some chalurate experiments have been carried out, appear to show that the plant has, to an extent the ability to remember. In this case it would appear that the falling of the light in the evening gives the signal of the developing of the leaders; it is found however that a bean plant which has been kept in the dark for a few days will continue to expand and close its leaf-lets at about the hours of sunset and souries. As Dr. Darwin had pointed out, we can evertainly red that the plant, or perhaps one ought to say the protoplasm in the cells, remembers that movements are carried out at certain times and these proceed even though the original silandius is warting.

Another very interveding problem in connection with vocations of the second of the question. Can plain for justice, the control of the question of the proter pair. Now, atthough that is a word with a definter asseming to human belings, it probably has a very the second of the probably has a very supertice as a second of the probably that a very the most case which would cause a man the most case with the probably has a very to a jobly dish; in the will have only a small descondror to a jobly dish; in the plant, can scarcely involve suffering in the sense in which can scarcely involve suffering in the sense in which can be called the prosent of the probable of the probable of the proposition of the probable of the probable of the writer had the opportunity of witnessing some very intreasing experiments with a senditive plant to demonstrate the extent to which the specimen might be said to feel win.

The example chosen was a young and vigorous plant of Mimosa pudica. Of course the degree of sensitive-

Leaves of a vigorous sensitive plant spread in normal condition before the application of a flame which touched for a portion of a second the tip of one of the leafists.

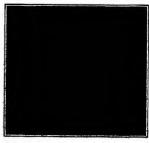

In the operation of chloroforming the sensitive plant, the liquid is poured on a piece of cotton wool, which is placed near the stalk.

ness is at its height when the leaves are in the most actively growing condition. The foliage was extremely responsive to cold air and the slightest touch, closing its lenders and dropping its statics with greet promptinde. It was ectabled, to try the influence of a finne minor the sensitive leaf. A piece of wadding asturated with apirit was set alight, and the finne was passed rapidly under a well-developed leaf. The organ could not have received more than a whiff of hot air, yet it gave very clear signs by the movements of its leaflest that a sensation, which we may call discomfort, had been produced. In the next experiment the finne was allowed for a fraction of a second to touch the tip of one of the leaflest. The outcome was autosiding; the whole leaf skrank as if it had experienced the most neutre pain.

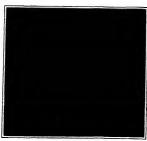

It was now decided to administer an anseshed: to the sensitive plant. For a long time it has been known that the mimosas are markedly affected by the vapors of chloroform and other. The method of administering the ansesthetic is on the following lines. The pot is which the plant is growing is buried in hay or some such substance. A large glass shade is then procured, which can be placed over the specimen. A good-stade piece of wadding is well soaked with the chioreform, or whetever the anesthetic may be; this is placed by the plant, and the whole is enveloped in the shade. After an interval of half am hour it is to be noticed that the foliage or the sensitive plant begins to droop. The leading squality close together, and finally the whole plant passes into a sleeping condition, even more protound than that which normally occurs when the light begins to fall. That the sensitive plant is "unconscious" there is the very best reason for belleving, seeing that it quite fails to respond to any touch. A more severe test still was the placing of the lighted wadding under one of the leaves. Here again it was evident that the ability to feel was quite in a state of suspension, just as completely as when an individual is under the influence of an anesthetic.

There is little doubt that, before long, we shall have yet further to revise our views concening the senations of plants. Of course for some time it has been excounted, for instance, that regetable tissue is coursely of a response to the stimuti of light and heat. It has slaway been argued than plants could not feet pain or discomfort because they have no nerves. The modern physiologist asks himself the question, what are nerves? To this there is only one naswer—modified and highly specialized protopiasm. We have seen that the life should not be able to act as a radimentary herrons system. As we how know the protopiasm in the plant should not be able to act as a radimentary herrons system. As we how know the protopiasm is not connect to the cells of the plant; ting strands of the living matter are able to peas through the walk, and thus keep up some sort of communication throughout the entire plant. These threads of protopiasm have often been spoken of as the nerves of the plant. This they are most decidedly, not in the britiary sense of the word. There is strong reason for believing that in some ways they carry out the functions which are usually performed by a nervous system.

A piece of cotton-west seaked in methylated spirit is ignited and held for a second ander the leaf of the sensitive plant. The last at sense closes.

# The Heavens in September

#### The International Union for Solar Research and the Astronomische Gesellschaft

By Henry Norris Russell, Ph. D.

IT would probably be a very good index of the degree of anyone's acquaintance with men of science if we could know what image was called up in his mind by the mention of an international scientific congress; and therefore it will bardly be necessary to tell th therefore it will bardly be necessary of the Scientific American that such meetings are of the Scientific American that such meetings are an american and american are a such as among the most enjoyable experiences—quite apart from matters of professional interest—that fall to the let of their members

A STATE OF THE STA

The writer is on his way home from two s erings, the meeting of the International Union for Solar ch, at Bonn, and that of the Astron sellschaft, at Humburg, immediately afterward.

The first of these was thoroughly cosmopolitan. Of the nearly ninety astronomers who attended the conference, scarcely one third were Germans. The Eng-ilsh-speaking delegates—divided aimost equally between the two sides of the Atlantic—made up another third of Of the remaining thirty, twelve were Frenchmen, five Russian, and the rest represented almost every other nation of Western Europe—Italy, Austria, Holland, Belgium, Spain, Denirk, Norway, and Finland.

In a body of such varied membership the proceedings necessarily take on a polyglot nature. English, French, and German are equally the official languages of the Union, and all business notices and formal motions are announced successive-ly in all three; while, during the discusslons, speeches in one language may be answered in another, with almost bewildorlug rapidity.

The regular proceedings of the Solar Union differ from those of many similar societies in that no formal papers are pre senied, though informal accounts of work done by individual members are sometimes The principal work of the organi gallon is done in the sessions of the unitie, with such subjects us the establishment of an accurate and uniform scale of standard wave-lengths of reference lines sludy of the Sun's rotation by spectroscopic methods; with the measurement of the Sun's radiation of heat; with the spectra of Sun-spots; and with the classification of the spectra of the stars. These committees, which may have as many as len or lifteen members, usually include all, or almost all, of the principal workers in their especial field, and their recommendations therefore come with an authorily which usually secures for them manimous acceptance.

The results of such committee work are rarely at all spectacular in character; but they save great expenditures of time and energy on the part of astronomical workers. For example, the committee on standard wave lengths were able to re port at Bonn to the effect that the measurements various observers in different countries gave results for the wave-lengths of the standard lines which agreed with one another, on the average, to within one part in two or three millions; so that a trustworthy and exceedingly accurate basis for future specire measurements is now in sight. On the other hand, the committee on the Solar Rotation announced that the comparison of the results obtained at different observatories showed certain small but "systematic" diff in the measured rate of the Sun's rotation—that is, it is found to be more rapid by some observers than by others, by an amount which, though very small, considerably exceeds the still smaller discordances b the results of measurements of different plates taken at the same observatory. In such a case as this, the caus of the differences must be found, and, if possible, r By exchanging plates siready mea observatory, between Ottawa and Mo suring them at the other, it was found that these the plates were taken, but in the measurement of the small displacements of the lines shown on the plates. It seems that in spite of all precautions one observer may measure the amount of this displacement greater or less—by an aimost infinitesimal quantity—than au-

ther observer does. investigations are still in progress, and there is resent to hope that these differences already ex-

Marie Marie and the second

ingly smail-may be brought to the vanishing point by suitable methods of observation. Meanwhile, the attention of observers is to be concentrated on the detection and removal of these small errors, leaving, until the time when they have been conquered, the study of such fine points as a possible difference in the rate of rotation of the Sun when measured by eans of the lines of hydrogen, of Iron, or of the heav-r elements. This may seem an unsatisfactory sort of report at first sight; but it is far better to know that amall errors exist, and to be out the track of their cause and remedy than to be going on accumulating with great paths and labor results which are infuenced by these errors; and without the general co-operation of all observers they might have remained undetected for

The committee in the classification of stellar spectra affords still another example of the advantages of cooperation. Up to the time of its appointment, there were three or four quite different methods of describing the spectra of the stars, all more or less in use

NIGHT SKY: SEPTEMBER AND OCTOBER

the first meeting of the committee, it was found to be the unanimous opinion of its members that the system of classification developed at Harvard was the best in existence, and should be adopted pending the construction of a perfected system, which must still be some years in the future. Correspondence with other astronomers brought out an almost unanimous agreement on this matter, and the recommendation of the committee was unanimously adopted by the Solar Union. In future, therefore, all astronomers, when discussing stellar spectra, will (so to spenk) be talking the sume ianguage, and much confusion will be avoided

The Astronomische Gessellschaft, though numbering upon its rolls astronomers of almost every nationality, is predominantly German in membership, and its proceedings are conducted in German Here, too, there were committee reports, dealing largely with the rebut there were also many formal papers, ranging over the whole field of theoretical and practical astronomy. As examples of the excellent work which is being

ne may be mentioned a paper by Dr. Rosenberg of done may be mentioned a paper by in tocessing of Libbingen, who has developed a new photometer, based upon the photo-electric effect (the emission of negative electrons from a metal surface under the action of Using a surface of potassium in vacuo he has ded in getting results which surpass in precision those of all previous instruments, even the selenium photometer with which Prof. Stebbins has had such

" Again, Prof. Hayn gave an account of a study of the shape of the Moon's limb, in which, by measuring upon

a long series of lunar photographs, the distances of many points of the edge from the center he has been able to construct a contour map of that region of the Moon's surface which forms its apparent edge under the varying angles of libration. This is not sloply of interest in itself, but will be of great value in the reduc-tion of linear observations. Suppose, for example, that an observer watches the occultation of a star behind the Moon, and records the exact instant of its disapnearance. Such observations, if the Moon were perfectly ud, would give us a very accurate deternduation of its position in the sky at the moment of observation irregularities of her surface, however, tutroduce serious errors. If the star happens to go belilled a mountain on the Moon's edge, it will obviously disap-pear sooner than if the surface were leveled off, if it strikes a deep valley, it will remain he sight longer By reference to Dr. Iiayn's map the computer can dete mine whether either of these things happened, and allow for the resulting error, so obtaining much more accurate results. The scientific side of these meetings accurate results

Important and interesting as it was hardly occupy a larger place in the memory of the delegates than the personal element. Public and private loopitality was of the most generons and delightful great German Bour, Cologue, and Hamburg—entertained the astronomers right royally, and our scientific hosts at the various observatories left us under an equal debt of kind-ness. And these festivities laid more of meading to them than the ordinary public One note was heard again and again in the addresses of welcome, and in the responses (which, token together, represented six or seven different languages), that of international good-will he such a gathering, where personal friendships add to the condion bond of scientific in-terest, differences of nation, race, and creed drop out of sight; and we may hone that they contribute their share, not only to the advancement of human knowledge, but to that of human brotherhood as well

The Heavens.
A glance at our map shows as what we may see in the evening sky. The great of Pegasos is high in the south Below it is the large but falut constellation Pisces, and the still larger, but more consulctions form of Cetus. right, low in the southern sky, is Fomilhant, which, though distinctly fainter than the standard first-magnitude star, is very conspicuous on account of its isolution. Aquarlus, above It, and Capricoraus, to

the westward, are dull constellations, the westward, are dull constellations. The far southern group of the Crane (Grus), which may now be seen below Fomalhaut on a clear night, would be conspicuous if viewed from a lower latitude.

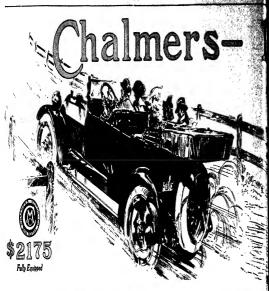

in the southwest, along the Milks Was, is a for ther on, Sagitturius (now brightened by the presence of Juniter) Is low on the horizon. Above it, all the way to Aquila, extend the great star clouds of the finest part of the Galuxs Was Still higher, west of the zenith, are Cygnus and Lyra Hercules and Corona Boreales are below the latter, and Optinchus and Boötes are setting. The Great Bear is low on the northern horizon, with the Dragon and the Little Bear above it. Auriga is rising in the northeast, and Persens and Auriga are above him in the Milky Way. Andromeda and Aries are high in the east, and Tourus is rising

#### The Planets.

Mercury is morning star until his conjunction with the Sun on the 16th, and evening star afterward, but he is practically invisible except at the very beginning of the month, when he can be seen, just before dawn, close to the bright star Reguins, which he greatly exceeds in brilliancy. Venus is also morning star. In Cancer and Leo, rising about 2:20 A. M on the 1st and 3.20 on the 30th. On the morning of the 25th she is very near Regulus, only about fifteen releates from him, and the star, bright as it is, will be almost lost

Mars too is nominally a morning star until he comes into quadrature with the Sun on October 2nd; but being very far north, in Gemini, he rises at 11 20 P. M. at

(Concluded on page 184.)

# South Carolina Thin Testing Olingo Chalmer No. Dentur - Dentur Arte Dentillo & B Collin Lammer No. Lawren Colubert - Lawren Seefs Debets

N official test was made, last month. A by M. Louis Biérlot, of a new brunching apparatus, particularly adapted for use on board ships and on land where the surface is too rough for the aeroplane to acquire the speed necessary to raise it off the ground. Two pairs of pules were erected 250 feet apart, the members of each pair being 65 feet apart and spanned by stont cables. Stretched between these spans was a main cable which formed the brunching track. On the flying ma chine a wooden frame was supported which terminated at its upper end in a pair of outwardly curving horns. At the vided which could be opened by pulling a Bieriot skilfully maneuvered the machine so that the borns would struddle the catle and the bitter would be caught under the If he wished to lannch the machine he set the propeller going and let it run along the cable until it had acquired suffcient speed, when he pulled the latch and ed the harlzontal rudder sufficient ly to pass under the end span of the cuble The apparatus calls for some very nice senvering on the part of the operator which might be absolutely impossible of achievement in gusty weather, particu-tarly if the wind did not happen to blow along the line of the cable

#### Where One Old Car Has Gone

"W HERE do nil the old cars go?" VV is a question that is usked con-tinually, and there are very few persons who can even approximate the answer with any degree of sutisfaction either to themselves or to others. But it is certain where at least one of them has gone for it is shown in all its new glory as a sedate lawn mower, by the accompanying The reason for its fall from aristo cratic to pleblan work is because its owner has a really tremendous lawn to keep in trim; he is head gurdener for a larg golf club and as every one knows putting greens must be kept "just so". There was an antiquated two-cylinder automobile on the premises that long had ceased to be of any practical value for pleasure purposes and the gardener conceived the bright idea of making it "die in the inrso to speak So with the help of some steel strips and some chains he attached no less than three lawn mowers to it—originally they were drawn by horses. The steering gear is intact except that the place of the front wheels is taken by a heavy roller; two rollers take the place of the driving wheels.

#### Bridge Erection Without Scaffold

THERE was a remarkable demonstra-tion of bridge construction at Hessen-winkel, near Berliu, recently. The bridge in question was nu fron road bridge of 150-foot span over the Milggelspree which at that point makes a sharp head and has rather violent currents. As a stationary scaffold would have interfered with the very heavy local pavigation, the contractors, Messes Breest & Company of Berilu, suggested erecting the whole bridge m land, and eventually moving it seroes the river by means of an ordinary burge of 200 tons carretty. The arrangements made to this effect comprised a stationury wooden trestle on each bank of the river and a guide path of double T girders and ratis connected therewith Having been placed on small from two-whee trucks, the bridge was on these guide paths moved out sufficiently for one end to rest on the wooden trestle lustailed on the barge. The barge, which had been weighted with sand, was then slowly un The barge, which had been londed and rose, lifting the bridge off the forward trucks. Then, resting on two trucks at the rear end, the bridge was moved on by means of wnoches histalled on the opposite bank (operated by four men) until its point reached the treatle on this bank. After supporting this point again on two trucks, the last advance over

Launching an Aeroplane from a cable the abutment stones was quickly made. The floating of the bridge across the structure occupied 11 minutes, during which time purlention bud to be engranded. The net weight of the bridge totaled about 80

capacity to return to their original fi when subjected to a strain. Upon what structural characters these qualities are endent is not separally known. and even science has not taught us very many useful facts about them. Amati. Stradivari, and others knew by expects the wood of spruce from the Alps pos sessed the quality of resonance to a mus greater degree than other woods wh made into a violis. The reason for this should be sought in the structure of the

Coniferons and broadlenf trees produ wood of widely different physical proper-ties, which are determined largely by the structure of the wood. Conferous woods are composed largely of vertically guted, closely packed wood fibers technically known as tracheids, and those of broadleaf trees are made up of wood wood-parenchyma fibers, and ves sels, all of which vary in size and thickness of wall. In the former the wood is simple in structure and in the latter it is very complex. Both groups of woods have horizontal rows of cells which extend from the pith or center of the stem to the bark. These are called pith rays. In coniferous woods these rays are usually only one row of cells wide, while in broadleaf trees they are often much wider. For instance, in the oak woods they are very conspicuous on a smooth transverse surface and often form nearly 30 per cent of the wood mass. The presence of these relatively large rays and porce or vessels in the wood of broudlenf trees naturally disturbs the regular arrangement of perpendicular elements, which is not the case in coniferous woods. The uniform structure combined with the great strength and clasticity of many conferous woods renm suitable for producing sound waves of different intensities. Of all our esses this native woods, the one that pass property of resonance more than any other ie spruce of the Northeast. This quality is to be found more especially in woods with perfectly straight fibers and narrow unual rings of growth of equal width. Defects such as knots, cross-grain, resin pockets, minute season checks, render the wood nufit for sounding boards. Very light woods with uniform structure comlined with great strength and elasticity are invariably selected for this purpose, and the spruces fill this requirement better than any other known

#### Contact System of Electric Haulage

I N a busy steel plant at Burnham, Pa . an electric hanlage system is being successfully operated day and night under the nost trying conditions. This hanlage sys tem uses neither trolley nor third rail, but surface contact made underneath the locomotive. As shown in the accompanying photograph the locumotive carries a contact rall, adapted to bear against boxes placed between the trucks. These boxes are so-spaced that at least one of them is always in contact with the contact rail. The contact loxes are flead, except when depressed by the contact rull, so that the system is absolutely safe at all times. The plant where this system is in operation is so crowded with furnaces, machinery and iron rolls that the tracks must be tantly crossed. Hot bars of iron from the furnices on one side of the track are being continually transferred to rolls on the other side. From the rolls the bars of white hot iron are passed back over the track again, so that the system receives two hot baths from every piece of iron that comes out of the furnace, and it becomes so hot that it is necessary, from time to time, to flood the roadbed with water. In another part of the mill enorwater. In another part of the minimum mous shears are in operation cutting our axies into the proper length for use in the furnaces. These shears are so near the axies into the proper length for use in pass are furnaces. These whears are so man the tracks that the heavy axies are frequently dropped on, the rails and piled up on boxes; yet the system is not harmed in any way. The absence of poles and over head wires makes this type of electrical A CONTRACTOR OF THE CONTRACTOR

# "It's funny what a difference a few Clothes Make!"

Simple Patent Law; Patent Office News; Notes on Trademarks

A few of the more prominent types of shock absorbers.

Fig. 1 Bibow type Fig. 2.-- Auxiliary spring Fig. 8.—Air cushion Fig. 4.—Einstie sbackio. Fig. 5.—Hydraulic. Fig. 6.—Rebound check. Fig. 7.—Pheumatic tire apring.

#### Shock Absorbers for Automobiles

ANY device attached to an automobile to prevent of the taw violent deflection of the springs of the correct or to eluminate the recul after deflection due to irregularities in the road surface, is commonly known as a stock theories. Automobiles, almost without exception, are equipped with semi-ciliptic, full ciliptic or three quarter ciliptics springs while are usually blacked alove the axies to irredde a flexible support for the body. These springs are usually designed so that the average or normal load on them will give the maximum deflection. This being the case, they will provide a proper inxible support for the body and give easy rilling qualities only within a certain range on either side of the normal load and maximum deflection. It was for the impuses of overcoming these difficulties that the sheek shocker was primarily designed.

Where the lead on the ear is considerably under the normal the edection will be very slight on account of the stiffness in the springs. Also, where the lead is excessive the detection will be violent. Shock absorbers are deshared to obviate both of these drawbacks, and may be generally divided into two main classes as follows 1. Those of the elastic spring shackle type for light loads, and 2, these which act as spring retardors or stiffners.

The various types of shock absorbers differ so widely in construction and operation that they may be properly subdivided into six classes as follows: 1 The cliow type: 2 Auxiliary spring type: 3 Preumatic 4 Elastic shade: 6 Hydraulic 6 Rebond checks. There are no less than forty different shock absorb-

There are no less than forty different shock absorbers on the market to-day, but as they are all included in the above six classes it is necessary to give a description of only one of each type. The device described is, in each case, shown in the accompanying illustration.

#### The Elbow Type of Shock Absorber.

In Fig. 1 is shown an example of the obow type of shock absorber which does not, like most of this type, depend upon friction for its resistance to motion. It completes of a triple, circular coil compensating spring, the ends of which need opposite sites of an adjustable stop, part of which is connected to one arm of the device and part to the other arm. A large center holf, 1½ inches in diameter, holds the case, cup, and two arms together, and is grooved to hold greate for intricating this joint. The triple spring is 14 inches long and on a 5-inch movement of the chassed spring its

total compression is only one fuch. Owing to its great length compared with its extreme morement during compression, there is little liability for breakage or that it will take a permanent set from its continued action. These shock absorbers are made especially to it a car of any weight, the tension of the spring being adjusted accordingly and the proper tension being held by the adjustable slop.

The Trufanit-Hartford is another absorber of the ellow type, though II does not employ the culled spring system. Most shock absorbers of this type operate on the friction principle. The Truffanit-Hartford was fully Illustrated and described in a former base of the Soukerite America's.

#### The Auxiliary Spring Type.

This device, linearised in Fig. 2, consists of a linear semi-clipick spring, made of circone-variandium steel. It is slightly more than half the length of the chaesies spring to which it is applied. It is invertible and is in line with the master leaf above which it lies no closely us to be scarcely noticeable. Interposed between it and the clauses spring, in the center, there is a short steel block just high enough to keep the overlanging tips of the spring just touching the upper surface of the master leaf when it is under normal load nosition.

When the chasels spring he compressed by a shock imparted to the wheel of the cur, the auxiliary does not touch it nor in any way affect it while it is bedge compressed, but out the reced the tips of the spring energy with the master leaf of the chasels spring as soon as it renches normal load position. At first it encares resulty, then with gradually increasing force, checks the reced until its sharp quick action is reduced to a stow casy motion and finally entirely overcome. The redsmost is reced its applied along the top of the master leaf of the chasels spring, thereby pre-tenting it from being jerked upward and away from its supplementary leaves by the inertia of the car body. With each oscillation of the chasels springs the absorber makes and browns contact with the master leaf, alsowing the little shocks entirely and protecting the body of the ear and the motor from harmful vibrates.

#### Paeumatic Air Cushion.

The graduated air cushion, Fig. 3, consists of a holithe cylinder, closed at both ende, in which a piston moves up and down. The lower cylinder head is provided with a universal ball joint and a clamp for consists of the modified in the cylinder head.

- Modella Carra. Pra. 11-1 baddanic Sira apringi

per cylinder head the piston rod passes through a gland and is connected by another universal joint to the channel frame of the car. Through small cylindrical holes in the cylinder walls, both above and below its center, air is alternately admitted and expelled from the cylinder. These ports are so located that the approach piston, as it moves on in one differents, will close them one after the other, until ail are closed, and finally, after all are closed, retain in that end of the cylinder a sufficient volume of air to act as a custion whenever the shock or recoil is excessive. During the closing process the pressure of the air in the cylinder is containtly increasing as one after the other the ports are closed, and in most cases of recoil the action never extends to closing all of the purts. This derive operates in both directions, assisting the spring to resist compression and checking the recoils.

The Westinghouse shock absorber may also be included in the pneumatic class. This device was described in a former issue.

#### The Elastic Shackle.

The elastic shackle type of shock absorber, shown in Fig. 4, is made up of two sets of four light weight, helical wire coils. Each pair of helical coiled springs are nested, the smaller inside of the larger, giving the appearance of only two helical coiled springs inside of each housing. Two housings containing these legislates of each shousing spring. They are unade after designs suitable for the various forms of leaf springs, as the elliptic semi-elliptic, three quarter elliptic, platform, etc. By referring to the drawing the reader will readily understand the construction, and eachton of these springs.

Do the ceilings of your plant reflect or absorb light? It makes a difference which you can figure up in good dollars. A difference in your lighting bills, in the efficiency of your employees, in the quality of your product.

You want all the daylight you can get—every manufacturer does. And you can get from 19 to 30 per cent more daylight, the amount of the increase depending on the present condition of your ceilings and walls.

### It is simply a matter of paint

Rice's Gloss Mill White Paint does not absorb a particle of light; it reflects every ray that comes in through your windows down on your machinery and into the dark corners of your plant. It will give you a smooth, glossy, tilelike surface, which will not scale off like a cold water paint; which will not crack or craze under the jar of heavy machinery, which sheds dust, doesn't soil easily and can be washed like enamel.

# RICE'S MILL WHITE

is economical to apply. It flows easily and evenly under a 4-inch brush. Its covering power and body make two coats equal three of lead and oil. It contains no lead or other poisonous substance, and stays white longer than any other gloss paint.

Rices's Mill White is an oil paint with all the advantages and none of the disadvantages of enamel. It provides the highest illuminating power and the greatest sanstary value at the least subject out.

We were the originators of "Mill White" Paint. None of the many imitations on the market is made by the special RICE process. Not one of them possesses the elastic, permanent qualities which made the reputation of "Mill White" Paint.

Rice's Mill White Paint is sold direct from our lactory in barrels containing sufficient paint to cover 20,000 square feet one coat. Write us, it you have that area or more of ceiling and wall space to cover.

#### Rice's Granolith

A tough and clastic, permanent finish for concrete walls. Becomes a part of the cement to which it is applied. One costs sufficient, unless a globe is desired. Makes into best possible primer on inside concrete and prick for a second cost of Elics \* Mill White Paint, giving a tile-like, enamel

#### Shock Absorber for Automobiles

(Concluded from page 192.) resulng the four nests of helical springs which vibrate so much more rapidly than the leaf springs, and act so promptly that they will bring the pin B back into normal position again before the shock has been felt in the body of the car. This absorber, like all of its type, of which there are several, is a very desirable refinement in automobile aprings, and when properly applied and kept in good order it is a valuable addition to the automobile equip-

The Hydraulic Type.

The shock absorber, shown in Fig. 5, onsists of a hollow cylinder A, the piston H, the washer valve I, with vertical sliding guide e-stops F, the hollow piston rod J containing the adjustable needle valve L for regulating the area of ports K, the combination packing-box-cap B, the eve etling the piston to the chi nel frame of the car and the eye G, for

connecting the cylinder to the axic.

Its action is as follows: Every complete movement of the chassis spring causes the piston to move first rapidly down in the cylinder and then slowly back again to normal load position, or slightly beyond. On the downward movement the oil in the lower end of the cylinder rush up through the large area ports in the piston, raising the valve I and gradually passing up into the chamber above the pis-When the downward movement of the piston ceases the valve I falls, closing the piston ports. The adjustable ports K, always open, have a communatively small area, which prevents the oil above the piston from returning quickly to the lower chamber, thus establishing a pres have in the upper chamber which varies in accordance with the severity of the jounce, and opposes the rapid return of the piston to its normal position, preventing excessive recoil of the spring

Another shock absorber of this type is two cylinders instead of one and is intended to take the place of the spring shackle This absorber may also be placed under class 4, as it combines both the hydraulic and the coll spring principles.

The Rebound Check.
The rebound checking device takes ef-

fect only on the recoil or up-stroke of the springs.

This device as will be seen by refer to Fig. 6, consists of a circular base divid ed in halves, one of which A, is part of the casting forming the clamp containing set screws G, by means of which it is xed to the channel frame of the car The other half B is movable and con talu a sleeve by which it is supported on a stud fastened in the casting A. This a stee is surrounded by a coll spring

C. The two-piece base is encircled
by four colls of fabric belting D
faced with a flexible brass friction band E attached by rivets to the inner end of the belt, and by means of its hooked inner end to the stationary half-base A The outer end of the belt D is looped arou the axie and fastened by the clamp H. The tension is regulated by taking up one or more holes in the lower end of the beit. The coiled belt, circular base, and coil spring are inclosed in a neat metal case which is shown partly cut away to illus

Its action is as follows: As the car springs compress the frame and axle move toward each other, and the coll spring C On the rebound the colled beit tightens and as the coils of beiting slide around over each other they create friction beeen the best D and the brass band E, which is wound around with the beit D in the coil. This friction gradually in-creases as the coils tighten and in most cases of rebound no other resistance is Nicolateff docks, which are of 12,000 tons ance is required, the action continues many is constructing a new type of marine until the two halves of the circular base motor of 8,000 horse-power size. England are forced together against the resistance already possesses boats of the "Envestores"

Pneumatic Tire Spring.
With this device the our rides as it were on pneumatic inner-tube tires without having them come in contact with the road and without the constant liability of punctures and kindred trouble

The accompanying illustration, Fig. 7. was made from a pl otograph of a tourwas made from a photograph of a tour-ing car on which these pneumatic tire springs were tested. To attach this de-vice to a car, the old axie clips are re-moved and the absorber elips substituted. From these clips is suspended a platform on which resis a segment of a pneumat tire containing an inner tube. A fran having a segment of the regulation clincher rim for engaging the tire, rests upon it, and on top of this frame the main semi-elliptic spring rests and is attached to it by the usual clips. Two air plungot visible in the Illustration located below the center of the leaf spring and work in cups formed in the axis clips.

They are provided to tone down a too
rapid action of the device. Each device is provided with the regulation air valve for inflating and deflating the air tube. The pneumatic tire spring shock absorb-

The pneuz er, being of the pneumatic type, really be longs in class 3, but it differs so widely in its construction and operation from any of the others mentioned above that it may be properly placed in a class by Itmelf.

Of the many other devices intended for reducing shock in an autominimum, there are few which diffe any great degree from those aiready described or mentioned, while there is probably none which differs in principle of

#### The Heavens in September

(Concluded from page 187.) the beginning, and 10:30 P. M. at the end of September. As the Earth overtakes him, he grows steadily brighter, and now he appears about equal to Procyon, though only one fifth as bright as he will seem at the end of the year.

Jupiter is on the opposite side of the heavens, and very far south, so that, though not yet in quadrature, he sets about 10:30 P. M. in the middle of the

Saturn is almost stationary in the w ern part of Taurus, and appears very like Capella, both in color and brightness. He is in quadrature with the Sun on the 10th. then Mars.

Uranus, which is in Capricornus (as described recently), remains above the horizon till about 1 A. M., but is best ob-

norman till about I A. M., but is best ob-servable in the evening. Neptune, in Gemini, rises about the same time that Uranus sets.

The Moon is in her first quarter at 8 A. M. on the 7th, full at 8 A. M. on the 15th, in her last quarter at 7 A. M or the 23rd, and new at midnight.on the 2 She is nearest us on the 1st, farthest away on the 15th, and nearest again on the 29th, when, from the coincidence of new moon and perigee, we may expect very high tides.

During the month she passes near Jupi-ter on the 9th, Uranus on the 11th, Saturn on the 22ud, Mars on the 23rd, Neptune on the 25th, Venus on the 27th, and h cury on the 30th. The conjunction with venus, which occurs about •4 P. M., is close, but both bodies are low in the west, under the Sun, and almost unobservable.

# All New Haynes Models

# have Vulcan electric gear shift as standard equipment

The Electric Gear Shift completes the electrical equipment of the Haynes. It is started by electricity, lighted by electricity and the gears are shifted by electricity. This wonderful invention puts an end to the pulling of gear levers. You sit erect, your hands never need to leave the steering wheel. Your eyes can always be fixed on the road ahead. Safety and confidence is gained as well as absolute ease and convenience—to say nothing of the satisfaction and pride in possessing the very latest of automobile betterments.

#### Many other good features

Mechanical tire pump, pressure feed gaso-line supply; complete dash board equipment as specifications show, rain vision; ventilating wind shield, wide doors and roomy tonneau; deep cushions, curtains adjustable from the seat, good-sized package space under both front and rear seats, and many other advantages-

#### Intra-countel Canal System for the Atlantic Seaboard (Concluded from page 186.)

The state of the s

the need for a completely sheltered waterway between Narraganaset Bay and Boston should receive further consideration. He was of the opinion that, after the conpletion of the Cape Cod Canal, the quetion of its acquirement by the Government, based upon its value as a going concern, might be worthy of further conaderation.

Waterway is what is known as the Narsett Bay-Long Island section. This route leaves Narragansett Bay at Bissel's Cove, and follows a series of tidal stream and lagoons to Long Island Sound, oppo site Montauk Point—one object of this diversion being to avoid the dangers of navigation around point Judith. The ganal 18 feet deep would cost \$11,300,205 and that one 25 feet would cost \$24.-736.635. The Special Board was favorable to the construction of the smaller canal; but the Board of Engineers of Rivers and Harbors differed from them believing that the canal afforded prac-tically no saving in distance over the out-side route, and that boats would probably prefer the latter, except in stormy weather They designated this as the "least-needed link" in the whole scheme. The chief of augmeers concurred with this view of the Board of Eugmeers, be lieving that the full benefit to be derived from the construction of a canal 18 feet deep could be obtained only on the com-pletion of the sections of the waterway to the south

The SCIENTIFIC AMERICAN is of the opinion that on the completion of the Cape Cod Canal, the protection afforded by Cape Cod Bay, Buzzard's Bay, and Loss bland Sound will be sufficient to meet the commercial necessities of the situation for many years to come.

New York—Delaware Canal.

Although the report of the Army Engineers is unfavorable to the construction of that part of the intra-coastal canal New York Harbor, they favor the con-struction by the Federal Government of the proposed waterway extending from New York to Beaufort. Regarding the New York Bay-Delaware River section, Special Board found that it would be inadvisable to purchase the existing Delaware and Baritan Canal, and they recommended that n new sea-level canal with a depth of 25 feet, connecting Barltan Bay with the Delaware at Treaton, be constructed at an estimated cost of \$45,000,000. The General Board, how ever, considered it improbable that the ercial benefits of a 25-foot sea-level canal 72 miles to length would warrant the large expenditure. They cludwed that, for the expected traffic of 5,600,000 tons, such a canal would show no advantage over a double-track freight railroad. The Board argued that, since the principal estimates for a saving by this route were based on calculations for one thousand and two thousand ton barges, and since either of these can be accommodated on n depth of 12 feet, it would be advisable for the present to build a canal of that

General Bitsby in bis report of August, 3918, recommends the construction of a lock causal, 12 feet deep and 90 feet wide, from New York Harbor to the Delaward Hiver, at a total cost of \$20,000,000. He suggests that it be no built as to provide for an economical enlargement to a depth of 25 feet, and for its outliness excession to see level. Bakes no Bitsby Character Bits See Section 12 feet of the section o

for its utilimite excavation to sen level. Delaware River-Cheaspask Bay Section. After examining all practicular routes in the section from the Delaware River to Cheanpeake Bay, the Special Board selected and surveyed a route along the line of the present Cheanpeake and Delaware Canal, which routhow from Delaware city on the river of that name, to Cheanpeake city at the head of Cheanpeake Bay. This examination showed that a quant 23 feet feets, along this route, would cost to build continued to the control of feets, along this route, would cost to build control of the control

80290,230 and the Board receivisheded that the Chesipseke and Delaware Canal should be acquired by purchase of 20,514, 284. This oanal is ten feet deep and is at the lock trop, the locks being 26 feet wide by 200 feet long. It was suggested that the change to 12 feet be made grad-ually, and in such way as to interfere as little as possible with existing traffic. General Bixby, in his recommendation made to Congress this month advises

made to Congress this month, advises that the Government should purchase the existing Chesapeake and Delaware Canai connecting the Chesapeake and Delaware Bays, at a cost not exceeding \$2,514,298. He further recommends the expenditure of approximately \$8,000,000 by the Gov ment in transforming this canal fro a lock canal into a sea-level canal with a depth of 12 feet throughout and a ninety-foot width at the bottom-the deepen ing of this canal to 25 feet being post poned until after the effect of the nev 12-foot canal on commerce is apparent
Norfolk-Beaufort Inlet Section.

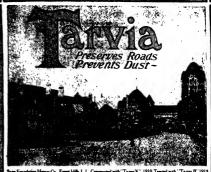

After examining all practical routes of the section from Norfolk to Beaufort, the Army Engineers selected and surveyed as marie and Chesapeake Canal, Currituck marie and Chesapeake Canal, Currituck Sound, Alligator River, Rose Bay, and Adams Queek. The plan was prepared for a canal having a depth of 12 feet and minimum bottom of 90 feet. It was recommended by the Special Board and approved by the Board of Engineers and the Uhief of Engineers, that the existing Albemarle and Chesapeake Canai should be purchased for \$500,000, and that \$2,235, on purchased for convoy, and that \$2,230.000 be spent for its improvement and the increase to a depth of 12 feet. The route from Albemarle Sound to Pamileo by way of Rose Bay was estimated to cost \$2, 215,000, the Brant Shoal cut would cost \$55,000 to remove, and the section of canal from Paulico Sound to Beaufort inlet via Adams Creek Canal was estimated to cost \$395,000. The estimated cost of con-struction of the whole section, exclusive of the purchase of the Albemarie and Chesa peake Canai, was \$5,400,000. Congress last year made a start in the construction of the Inter-coastal Waterways by ap-propriating \$400,000 for this Norfolk Beaufort section, \$500,000 of this amount to be expended in the purchase of the Albemarle and Chesapeake Causi, the bala to go toward active construction.

Existing Conditions.

The situation then with regard to the porposed inter-coastal Waterway, is that the section from Boston to New York is the section from Boston to New York is abandoned; that the Chief of Engineers has recommended that Congress appro-priate \$30,000,000 for the construction of printe explosion for the construction of a 12-foot canal between New York and Norfolk; and that the 12-foot canal from Norfolk to Beaufort, as we have said, has been authorised by Congress and is now under construction.

#### Life Without Microbes

THE possibility of animal life under conditions quite free from microbes is occupying the attention of experiment-ers, and the Paris scientist Guyenot uses the common fly for this purpose (Droso phila ampelophila) obtaining their reproduction and following their descendants. He now possesses a collection of speci-mens dating from two years past and comprising a great number of generation Development from the egg to the image, at 24 deg. Cent., lasts for twelve days. and the femates commence to lay on the first and second days after hatching. In this way be obtains two generations a this way be obtains two generations a month and each generation contains at least 10,000 files. The line followed by him since May, 1911, includes some 40 generations or 400,000 specimens. Under these conditions, living in a medium free from microbes and feeding upon specially prepared food, the specimens do not show prepared food, the specimens do not show any leasoning to attempt of fecundity. But ou the contrary their development taking place under exceptional conditions which are not found in nature. Wille in this critisary case the increatity during de-velopment in when great for have and rouns at its semediatity making in the pre-

# **Dust is Expensive**

WHEN an automobile speeds While I an automobile speeds down an ordinary macadam road it leaves in its wake a cloud of dust which is carried by the winds over the neighboring fields, houses

over the neighboring fields, houses and lawns.

This is just as surely a waste of good material as if the automobilist dug material out of the highway and carted if away. Dust represents waste—cody waste—and the taxpayers feel the result. A road that is properly built for modern traffic will not be dusty.

Plain meadam gives way under the wear and tear of heavy rubber-tired automobile wheels and the surface binder of the road is torn away in

the form of dust until in time the co stone itself is exposed and a costly renewal of the road is necessary.

Modem roads should be built to resist modern traffic. To build any other kind is wasteful. A better binder than the ordinary mineral binder is needed and is offered in Tarvia, a coal tar compound espe-

cially prepared for use on roads.

Tarvia is dense, viscid, water-proof. It fills the interstices between proof. It hils the interatices between the stone and forms a tough, plastic matrix. This makes a waterproof and automobile-proof surface. The maintenance cost is usually so low as to more than balance the cost of, Tarvia treatment.

#### Automobile and Improved Roads (Concluded from page 178.)

tions which are most carefully laid in one course and some of which have been given a paint coat of bituminous materiat; and fourteen sections of brick pavement laid on six inches of concrete with as many varieties of modern paving brick. Preliminary measurements of all quantities have been made on this work, and a very careful traffic census is now kept.

#### The Natural Sell Read and Its Possibili

Curlously enough we are forced to admit there is a possibility that the natural soil road will play an important part in the future. The natural soil road well drained and crowned is a most comfortable road during a large part of the year.
Will it not be economical to give the earth d gravel road a thorough trial? In the past gravel and earth roads have not been past gravel and earth roads have not been scientifically cared for. It is now known that, with persistent drugging, natural soil roads may be kept in splendid condi-tion except in the very worst weather. It has not yet been demonstrated that an earth road built with the same care for grading, silgament and drainage strucat would be given to a bituminous macadam road, or a brick road, may not. macadam road, or a brick road, may not, after all, be a very economical type of road if properly maintained. If traffic on such a road develops in the future, there will be an excellent foundation for a superior surface. One reason that natural soil roads have not been considered by modern highway engineers is because such roads have never been maintained with sufficient continuity and care to demonstrate what they can do. There is no doubt that a well-built sand-clay road, where the materials are carefully selected, is a most excellent highway. It will stand up under considerable traffic, and is very comfortable for automobiling. Of course, such a road must be maintained by skilled labor continuously. The most economical method of annual

or skined abor continuously. The most eventuation in the hold of annual maintenance of our bituminous bound macadam roads has not been finally determined. Last year and this year saw the first scartifying of old bituminous bound roads to any extent. From now on, there will begin to supear the necessity for resurfacing bituminous macadam highways, as some of the first roads so built are now seven or eight years old. Evidence presented at the international Road Congress in London, tends to show that high carbon tar products used for the superficial coat upon highways, tend to become weathered and are less waterproof than some of the asphaltite oils. This eridence however is not conclusive. Over a great many miles of bituminous macadam State roads in New England, a very light cost of oil has been applied twice a sosson where automobile traffic wheevy. The oil has been put on regardless of the dust, and forms a soft, loose layer of oil and loose of layer of oil and forms a soft, loose layer of oil and loose of layer of oil and

#### Automobile Economics and Good Roads

When it comes to the economic benoft of the automobile, we face a problem comparable to the problem of the value of railroad transportation. The movement of passenger coaches is not always of direct economic value, and yet such transportation is an absolutely mecessary feature of our modern life. It is quite common to hear it stated that the automobile is a pleasure vehicle. In the beginning of the automobile movement, the pleasure travel was doubtless very large, but it is certainly not true to-day that motor vehicles other thau trucks are all pleasure vehicles. A large number of them are used for business purposes, in the same sense that the railroad car is so used. There has been an extensive readjustment of land values in many parts of the capture of the suppose of the subject to the subject of the suppose.

and, speed in travel all over the co (17) has have dumness development. Of course, no one denies that a large part of automobile travel is still purely for recreation and enjoyment. The need of organized recreation and enjoyment for the more densely populated areas of this country cannot be denied. The automobile count of highways is merely an incident which indicates the directions in which our people are willing to increase their

Perhaps of more direct ec ee than any item which has yet appeared is the increasing use of the aut mobile truck in farming operations. A ples are hauled by motor truck in Virginia and Oregon, cotton in Mississippi, potatoes in Maine, and so on. The possibilities of increasing the service of motor trucks in collecting cream, transporting perish able fruits, and kindred operations are im mense. When the use of such trucks be comes common, the construction of roads will have reached a more scientific stage than ever before because the demand for such service will be exacting. While thinking on these matters it must be re membered that progress in the economic development of transportation and distri-bution methods is an essential and inevitable feature of our modern life.

The Third American Road Congress which occurs in Detroit, September 29 to October 4, inclusive, will have one section devoted entirely to the discussion of the technical features of highway engineer ing. As there will be present at this gath ering most of the highway commission of the States actively engaged in road building, there should result from the meeting many valuable conclusions as to the present stage of construction and metutanence

#### The Winnipeg Tractor Trials Sixth Annual Event Shows Farm

Ready for General-purpose

Engines

By L. W. Ellis

THE sixth annual farm tractor compe-tition held recently at Winnings brought out the fact that, even in the vast prairie provinces of Western Canada, boti farmers and manufacturers have satisfied elves of the efficiency and economy of the larger, standard type of tractor and are now more keenly interested in the medium to small tractor for general work

A glance backward over the six cur-ests shows a marvelously rapid evolution of the modern tractor from the experi-mental to the every-day stage. The present year's trials seemed to prove that from the psymiar standpoint, at least, the element of uncertainty was so lacking as to result in an almost complete iapse of interest. As if by common consent, farmers and manufacturers suddenly withdres their support, and the competition am only three firms had more of a technical than a popular significance.

The first contest, in 1908, was an ternal-combustion tractors only, the weight limit of seven tous barring practiculty everything in the way of a steam engine. The very large gullery that watched the hauling and plowing trials had quite as much interest in seeing whether all the tractors would fluish the tests as in the comparative scores. Their viewpoint was substantiat, for only six out of seven finished, and nearly all had difficulties that would have proved serious in actual practice.

After 1908, steam tractors were and for two years the battle was between the ponderous old steam engine and the lighter internal combustion rivats which had sprung up thickly and with growing satisfaction to the trade. The introducon of a friction brake as a substitute for 1. 16. SHOOK ABSORBER CO., Inc.

180 S. 17th Stoney, Philodophia San the state of the second

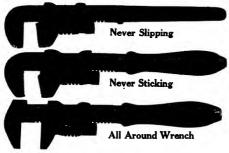

This new Winchester is the lightest, strongest and handsomest repeating shotgun made. It weighs only about 51/4 pounds, yet it has surpassing strength, as all the metal parts are made of Nickel steel, having about 50,000 pounds more tensile strength to the square inch than ordinary steel. The receiver is free from screws and unsightly pins to collect rust and dirt and work loose, and its solid breech, closed at the rear, makes it extremely safe. It operates and works with an ease and smoothness not found in similar guns of other makes. It is simple to load and unload, easy to take down, being separated into two parts quickly without tools. For pattern and penetration, it is fully up to the established Winchester standard of shooting quality, which has no superior.

Ask your dealer to show you one, or send to Winchester Repeating Arms Co., New Haven, Conn., for illustrated circular.

A 20 GAUGE GUN FROM BUTT TO MUZZLE.

### THE UNIVERSAL WRENCH

THE ONLY DURABLE, QUICK ADJUSTABLE SCREW AND NUT WRENCH MADE

IT fills its place more perfectly in the great progress of mechanical art than any ownersh or tool ever invented. The present age, greater in schievement than all ages, demands greater speed and accuracy, and greater production in every lin

human endeavor.

THE UNIVERSAL WRENCH has been recognised and pronounced by all workmen from master mechanic to the man at the banch, the strongest, quickest to adjust and sever-failing Wrench now on the market and the only Wrenche assevering the demand for increased production. As a Pips-Wrench the Universal positively has negatil in any particular, with its alidable and removable javs the advantages are too plain and self-evident to the average mechanic to permit comparison with other Wrenches. This Wrench is now being manufactured by The Universal Wrench Company of Portland, Oregon, owners of the United States Patents, in their new and commedious factory, with a capacity of 500,000 veraches annually.

FOREIGN PATENTS VALUABLE

All communications with this company and for foreign patents of this marvelous tool should be addressed to the inventors, C. F. and C. G. Youngquist, 442 ½ Washington Street, Pertland, Oregon.

steam tractors lay help

the scenn tractors lay nemies for want of water wishin sight of a large, modern city, was not without its effect. The combatants became the advocates of gasoline and karosene, respectively sene entry in 1910, the nun From one revenue entry in 1910, the inter-ber became eight in 1911. A year later kerosene—the cheap fuel—won the fight, fust as gasoline, the labor-saver, had first won over coal. Higher engineering effisiency in the gasoline tract prevail against the practical commercial odds that placed a handicap of nine cents a gallon—27 to 30 cents an acre—against ratory skill.

With these contests decided, and both kerosene and gasoline tractors growing in reliability to the satisfaction of the customer, the five-to-one ratio of internal stion to steam tractors for plowing now seem to make further contests up necessary for settling the broader, general questions. The decision as to the merits of particular makes of machine is ever one that must be settled on its merits for each locality, and even each form, by itself, owing to the great variety in type and adaptability of model offered the public

Press and public had turned their tion to the one great question remaining comparison of the tractor with the mained practically the same this year and promised no new light upon the ques-tion of the hour. The busy manufacturer and the blass farmer stayed at home, a three competitors, with the usual attend of technical representatives, had the field to themselves. These were the J. l. Case Threshing Machine Company, Ra-cine, Wis.; Avery Company, Peoris, Ill; and Sawyer-Massey Company, Toronto Canada; Rumely; International Harvest Emerson-Brantingham: Kinnard-Shapely and Muir; Marshall; and other ormer contestants, dropped ont and, for the most part, contented themselves with

the most part, contented themselves with displays at the exhibition proper. As usual, many new models appeared. From the inside, the competition was well conducted. The Canadian Industrial Exhibition, the sponsors, provided satisfactory facilities, and the conduct of the conduction test by members of the American Society cultural Engineers, acting as such, high order Prof. L. W. Chase of was of high order was of high order Prof. L. W. Chase of the University of Nebraska, acted as engi-neer-in-charge. The judges were Prof. J. B. Davidson of Iowa State College, Prof. L. J. Smith of Manitoba Agricultural Coliege, and Prof. H. W. Riley of Cornell University, former president of the so-Each of those centlemen heads a ment of farm engineering, and the corps of observers was composed of advanced students in agricultural engineer-ing from the Manitoba institution, each one with the advantage of at least one year's motor contest experience. As a result, the data obtained are unusually complete and reliable, easily outranking those taken at any of the European trials which are being held with greater fre quency each year.

The basis of competition was practic ally unchanged from that of other years except that definite, previously annous penalties were set for definite faults. Two competitors, each having entries in the same two classes, exchanged first prize gold medals as a result of penalties, without either losing an honor, but otherwise the deductions did not affect the relative standings. The tests consisted as usual of four phases:

(a) A two-hour economy brake test for ny of fuel and water, steadiness of g. absence of mechanical trouble or running, absence of mec excessive inbrication, etc.

(b) A half-hour maximum brake test immediately following, to determine the highest feasible power output, i. e., without excessive consumption of supplies, vibration, heating of bearings, lubrication, or other difficulty, and without increasing ne speed.

(c) A plowing test of from three to five hours, for economy, tractive efficiency, capacity (in noise per hour and power onignet, quality of work, and the distance traveled without replectables, sengation.

(6) A correction comparison of design and contraction by the experis mentioned. Out of 500 points, the economy brakes was alloted 150; the maximum brakes best, 50; the plowing test, 200; and the inspection test, 100. The highest not score was 4873 points, and the lowest. 154,05 points, this last tractor enferring a total of 178,88 points in deductions from the gross. The heaviest deductions on the tractors as a class came from stops after starting tests, unswer speed, hot the tractors as a class came from stops after starting tests, uneven speed, hot learings, vibration, lack of water capac-ity for an 8-hour run, and failure to keep the plows in the ground throughout the

The showing at the brake was quite uniformly good, developing some very close scores. Little distinction was made betion; hence the awards were settled wher the average spectator likes to see then settled, i. c., upon the plowing field. The appended table, condensed from the offi-cial tables, and with bewildering extraplace decimals excluded, shows briefly the most important points of comparison, the total scores, and the relative standings (The official tables show comparative per formance or score on 178 points—a mass of figures that make better reading for the engineer than the layman.)

Onip one tractor failed to win either a diploma (in a case of no competition) or a gold, silver or brouze medal. Case won seven gold medals and one silver medal, Avery, three silver medals and a brouze medal; and Sawyer-Massey, one gold medal and three silver medals. In a separate test for engine gaug plows, Caswon two gold medals, and Avery two sil

A new feature in the observing was the use of a vibration detector, ingeniously devised from part of a steam eaglise in-dicator and the necessary llukage. White the apparatus was crude and provision for ching it uniformly to all engines wa lacking, it gave a fair basis for comparison. Penalties of from half a point to èven points were laid as a result.

The most severe criticisms on design and construction were on lubricating avatems and insufficient protection of work ing parts from mud and dust. Tractors specially of the internal combustion va riety, have had the greatest attention paid up to date to the matters of reliability, ease of handling, and economy of fuel Now the tendency is plainly toward a gradual refinement, both to enhance the features sirendy mentioned and to pro vide for greater durability

For the first time, the plowing tests were held in ground that had been plowed before. The furrows were deeper for agricultural reasons, and not so smooth as in cultural reasons, and not so smooth as in the virgin sod of former years A two-foot growth of weeds presented a new, practical problem, to which emergency, however, the plowmen were fully equal The engine steering guide, a boun to the and engine steering know, a bonn of waingle-handed operator who works as true tioneer and plowman both, was not used, evidently because no one cared to risk using the extra fuel useded to push it abead of the tractor. However, the most exrienced tractioneers on the side lines held that by its use, even in such a con test, the tractioneer could have given hot-ter attention to his motor and probably more than offset the added burden by se-

curing greater fuel efficiency. The gas tractor men suffered in two particulars from the very advantages which have made their product such a aful competitor of the long-estab successful competitor or the lished steamer, viz., penalties for failure to carry au 8 hours' water supply, a point which was not even scored on the steam tractors; and labor costs, which were not added to the fuel costs in obtaining the operating expense per acre. The gas trac-tor, either kerosene or gasoline, saves one man, the fireman, but even without this gain the average cost per scre for steam essines was only a trifle lower than for Bercosne, I. e., 443 cents, compared to 500.

Cents The gasoline strenge was considerably higher, Ch.I. cents. The plowing was not so difficult on in 1912, yet not so the foreign call the cent as law.

#### Reaping the Whirlwind

ISREGARDING the secondary or immediate causes of the succession of frightful disasters on the New Haven Railroad which has cul-minated in the recent wreck near North Haven, Conminuted in the recent wreck near North invent, con-nection, and taking a broad view of the whole situa-tion, it may be said that these disasters are the bitter fruit of the policy under which the great system has been controlled during the just decade. As proof of this we submit the following propositions:

1 In the event of collision, a modern express pas-senger train, say, of ten Pullmans, drawn by one of train, say, of ten furnishing, drawn by one of the latest heavy express engline, represents when morning at 60 miles per hour, a smashing energy equal to twice that of a 12-inch projectite/discharged from a state of the drawn of the control of th modern dreadnaught

modern dreadmought
2. Since the neciteirals impact of this flying mass, with its precious human fredsht, would mean the instantineous development of over 100,000 functions of energy, it is evident that the very first consideration of good rallroad management should be to provide for its amouth and sufe transit from place to place, by making use of every known physical and human precausion against derollment or collision. .

In view of the inestimable value of the horns freight curried and the enormous and ever insistent perlis which beset these heavy and fast-fixing trains, it becomes the duty of the directors of the road to give it becomes the duty of the directors of the band to give the question of sufe construction and operation the first blace to see to, it that the first appropriations from the trensury are those which are made for the unsintenance in absolutely first-class condition of tracks,

rolling stock, and gameral equipment.

4 Since the risk of travel are broadly propor tional to the density of travel, it follows that the duty of maintaining the physical properties in absointely first-class condition is particularly imperative in the case of railroad systems such as the New Haven Railroad, whose passenger traffic is one of the densest

and most renumerative in the world.

5. Sp far as the truck and roadbed are concerned, the dangers of fast passenger travel may be reduced to a minimum by the provision of heavy and well spiced rails, with the plates interposed between rail hase and tie; by the close spacing of the ties, and the maintaining of them, by continual renewals, in first-class condition; by the provision of ample stone ballast; by the con-tinual improvement of the track through the removal or easement of sharp curves, and the maintenance of outer rails on curves at their proper superelevation; and by the elimination of old-fashloned cross-overs with abrupt turnouts, and the substitution of long cross overs, suitable to modern, high-speed traffic.

ti For the prevention of collision it is abs necessary to mulidula between these heavy and fast-flying trains a proper time and space interval, and to provide a system of signals by which it will be impossible rule a system of signors or which if will be impossible for successive trains to come within certain specified distances of each other. Since the introduction of the block signal system has offered a means of doing this with practically absolute certainty, it is the duty of the directorate of a first-class and wealthy railroad to see to it that its signal system is of the latest and most perfect pattern, and to see to it, also, that the running rules are such as to prevent any playing fast-and-loose with the automatic mandates of this mechanism as

thus applied.
7 Since the protective value of signals depends upon the intelligence and discipline of the train crew, and collisions due to human fallibility are frequent, it becomes the duty of good management to reinforce its block-signal water with some form of automatic ston which will correct the mistakes or care

stop, which will correct the mistakes or caressesses or the train crew, and enable the signal mechanism to stop a train should the engineman fail to do so. 8. The most perfect equipment is liable to failure, and collisions may occur on an absolutely final-class road. Hence it becomes the duty of good management to mitigate the dissatrous effects of gollision (by buildto mitgate the disastrous energy of sometimes in a distribution ing its rolling stock of such astronath and of such materials, that the killing and womating due to such collisions will be reduced to a missionum. Since the exalready had with steel cars has shown them to be a most effective protection to the passengers in the event of collision, it is evident that a conscientious directorate and management will bend every effort to the earliest possible substitutions of a steel for a wooden car equipment.

9. Finally, realizing how greatly the efficiency of the most perfectly built and equipped road depends upon the human element, an elicient management will do its utmost to maintain a high standard of discipline among the employees; and knowing that the unidare to face the public opprobrium which would fall upon them if they endeavored to bring about the reinstatement of an employee who had been discharged for disobedience of rules, an efficient management will see to it also that its subordinate officials are always strongly sustained when an employee is discharged for an infraction of the rules.

Ten years ago the great railway system which has recently attained such an uneuviable notorfort for the number and magnitude of its railroad wrecks, was one of the best equipped and best operated railroads in the country. The character of its roadbed and rolling country. The character of its roadbed and rolling stock and the general safety of its operatible compared well with those of other leading railroads—a condition of affairs which was reflected in the high quotation of lits bonds and stocks in the money market. At that, time, however, there was change of management and directorate policy to which, more than anything class. are to be attributed the present deplorable conditions

There was conceived and put in operation an am-bitious scheme for the shutting out of competition and the acquirement of a complete monopoly of transpor-tation, which was revealed in the wholesale buying up of all possible means of transportation, whether by up of all possions means of transportation, whether by ruil, trolley, river, or neean. Appropriations which should have been made for the improvement of the existing randbed and the construction of additional tracks to accommodate the rapidly growing traffic; for the elimination of short cross-overs and other defects of track inyout which had been left over from earlier years; for the bringing of the rolling stock up to modern standards; for the substitution of steel for wooden cars; for the development of the block signal system; and for the thousand-and-one improvements which are equitinually necessary to meet the conditions of firstoutrinually necessary to meet the conditions of nea-class ralinoading as outlined in the several propositions above given—these appropriations must necessarily have been diverted very largely to furthering the ambi-tious scheme of culargement and consolidation to which we have referred.

emporaneously with this curtailment in the fund applied to the physical upkeep and improvement of the properties, there has undoubtedly been a deterlor-ation in the discipline of the road. Anyone who has ation in the discipline of the road. Anytine who has followed enscribility the various official investigations of the many railroad wrecks of the past two years must have been convinced of this. The frequent overrunning of signals, the placing of comparatively raw men in charge of important express trains, the failure of fingmen to go back over the distances specified for the protection of trains, coupled with the continual complaint of the management that it was hampered by the unions in the effective maintenance of discipline, suggests that in its anxiety to prevent the great loss of revenue du to strikes, there may have been a fallure on the part of the officials higher up to give that hearty en-dorsement which is necessary, if the lower officials are to hold their men rigidly to the rules and regulation

of the pending official investigations, it would be out of place to give any definite opinion as to the immediate causes of the recent accident; but there are certain facts, of public knowledge, which are sufficient to explain the terrible loss of life which occurred. We refer to the old "banjo" system of signals, extremely difficult to see under the condition of Tog which pre-valled at the time of the accident; to the fact that the flagman went back only 440 feet when he should have e back half a mile; to the absence from the heavy train of Pullmans of a single car of steel construction; and to the fact that the engineman was running much faster than he should have done under the weather

The Natural Time Unit in the Organic World Nour days all sciences, including blology, have become quantitative. We no longer ask merely, what he been the course of evolution in the past, but we particularis—we ask what is the age of the human ruce? or, how long must it have taken for man to evolve from a primitive as vary condition is the pre-civitized state? In the times required from require state by the theory of evolution in homeour which which know of the age of the earth with the entryit, profile arrata? For it must be recommended, then, their great this age may be, it is not all indicate and if we to accept the theory of evolution, we show that the viscost that there has been time for the con-changes to have been time for the con-changes to have been the time of the

theory.

Now, whether we suppose that new species arise by
the gradual accumulation of slight variations of the
offspring as compared with the parent, or whether we assume that mutation—sudden radies! departures from the parent stock—play an important part, in either case the natural time unit to employ is the average length of one generation, or, to be more exact, ti age difference between the age of the parent and its off-spring. For the number of cumulative variations in a given line of descent in a given time cannot exceed the or of generations in that time. Let us take an illuminuting concrete example. If you, the reader, con minuting concrete example. If you, the reader, could gather foughter every one of your made innectors in direct line of descent, back to the year core of our present rectioning, you would see before you a small band of not more than about eithy-five men! Even assuming that there had been, during these less 1000 years, a continuous variation in one direction in some characteristic of your anearty, you would hardly expect your great grandfather sixty-five-times-removed to be very different from the men of our time, as not as he is not a first very different from the men of our time, so far as his biological make-up was concerned.

But with the lower organisms the situation is very officient. In the case of the house-fly the length of one generation is about 12 days, and in the recent experiment of Guyenot, a line started in May, 1911, has now passed its fortieth generation—representing about 1200 years of human history. And this is a mere trife as years of human history. And this is a mere trife as combaried with the conditions prestilling among very low forms of life. Miss L. L. Woodruff isolated a parametrian (slipper unimatedne) on May 1st, 1907, and carefully followed up its progeny. In the five years from the date of inception of the observations, to 1912, as connected and the triple of the Scotch power, and absolutely unthinkable multitude, and their volume, had they all been preserved, would have been about ten thousand times that of the earth. With such rapid succession of, generations we may well expect marked evolutionary changes within historic times, or even within the course of a few years.

# The Aviation Lessons Taught by the Tripolitan and Balkan Campaigns

HE lessons taught in recent European army maneuvers were confirmed and corrected in the Balkans. France and Germany are already fully equipped and organized for waging real aerial war, the one in aeroplanes, the other in dirigibles. The maneuv of Austria and of England have shown that they too are prepared, although to a more limited extent

The wer in Tripoli taught us more of the possibilities of aircraft than the campaign in the Balkans. In Tripoli the climatic and geographic conditions were so favorable that, despite an utter lack of aerial organizaition, the Italians were singularly successful in the air. In the Balkans, the climate, local conditions, and the geographic panorams offered difficulties which showed the absolute necessity of an organization of the kind thus far wholly provided for only by France and only partially by Gers Germany.
nents of the Italians in Tripoli were com-

The opponents of the Italians in Tripoil were com-posed chiefly of Arabian irregulars and comparatively small Turkish forces of regulars. In the Balkans, on the other hand, there were on both sides great masses of regular troops, improved artillery in great quantity and strong fortifications. In Tripoli the aeropianes, much to their advantage, were glways able to return

much to their advantage, were always able to return to the same camp, where they could be well cared for. Tripol is a sandy desert, quite flat, with an occa-sional oasis. Actual fighting there was confined to a sional ossis. Actual aghitug there was confined to a comparatively small area. The scroplance were not even required to follow troops on excended marches, because there was no object to march for. The coun-try has no resources, few cities and only a feeding population living in tests and shirtings from easily to cases. The enemy was naturally very sitesty. Forces of arabian irregulars appeared to-day only by disburial again to-morrow. Hence the six society sides of the lard put to if to find them; but in this task the simple try of the landscape and the marregionity sides at week.

of great-applicance.

#### Electricity

The state of the s

Westminster Abbey Electrically Lighted.—During the occunation of King Edward VII, in 1902, Westminster Abbey was temporarily equipped with electric lights. Again electric lights were used at the occuration of King George V. Now the temporary installation has been enlarged and made permanent. The Abbey is equipped with 50-watt, 226-wott metal filament kamps, operated on a 200-wolt drown. The organ is also provided with two blowers, each driven by a 514-horse-power motor, operated on a 400-volt circuit.

The Wireless Statish on Macquaris Island, which me established by Dr. Mawon's antarotic expedition, is suported to have been taken over by the government of Statistics to serve as a permanent westber station. Of Statistic midway between Australia and the autoretic continent, its reports will be of immense value to the weather forecaster of the commonwealth. The meteorological outpoot maintained by the Argentine government in the South Oriencys, in a higher lattitude than Macquaris, has not at present any telegraphic outminisation with the world, but the excellent of a wireless station there has become a practical quegion on secount of the important which failuries in that violatity.

Wiesless and Westker.—Writing in a recent number of the Beletical World. A. H. Taylor tells of his investigation of the effects of weaker. All Taylor tells of his investigation of the effect of weather on the transmission is in almost every case particularly favorable when cloudy weather prevails between the communicating stations. When the area is only partly cloudy he is inclined to think that transmissivity is better when the sun is shining upon the receiving station and its neighborhood rather than the vicinity of the transmitting station. But in such case the transmissivity is not so good as when the cloudy area includes both receiving and transmitting stations.

To Effective the Norfelk and Westers Railread.—

To Electrify the Norfolk and Western Railread.—
Contracts have been let by the Norfolk and Western Railread.—
Contracts have been let by the Norfolk and Western Railread to electrify the Bluefield-Virian section, which is 55 miles in length. An overhead toolley system will be used like that of the New York, New Haren and Hartford Railread. Single-phase 25-eyele alternating current will be supplied at 11,000 voits presence. Over this line 55,000 tons of ocal are handled per day. Twenty-six 130-ton cloetrio locomorives have been ordered, adapted to run at speeds of from 7 to 26 miles per hour. The line includes a 3,000-00t tunnel, which is very difficult to ventilate. The electrification of the line is to be completed next summer.

Dementia Telephonica.—An indiscreet Berlin lawyer any Medical News was adjudged guilty of slandering the post-office administration, which controls the telephone system under the Teutonio polity. The particular offense of this Berlin astorney was that he called telephone grits "camels" and "absep." The culput's dense was that telephone operators delight to torture the violus at the end of the wire; one day he had called a number nine times within three quarters of an hour and each time had received the tantalizing answer that "the wire is busy"; complaining then to the central manager he learned that his connection had been free all the while. The court's medical expert testified after an examination of the defendant that the latter was of a highly nervous temperament, and that there were asses of mer who had gone insise from telephonic wexation (Telephonicges), but that neverthelose he had not as yet passed the state of legal responsibility. He was fined 200 marks (865).

but that nevertheless he had not as yet passed the state of legal responsibility. He was fined 200 marks (2805). Chrona-Platographs of Hertaian Waves have been made with great precision by H. Abraham with his new apparatus that includes a Carpentier galvanometer designand for rapid movements which reference and only the same and the process of the waves. #### Science

A School of Pisciculture is to be established by the rovincial agricultural council of Bohemia at Eger.

The Largest Searchlight in the World will, it is reported, be installed on Mount Tamalpais as a feature of the Panama-Pacific Exposition.

The Mawson Reliaf Expedition, commanded by Capt. J. K. Davis, is to sail from Melbourne for Mawson's headquarters at Commonwealth Bay the last week of November, and hopes to be back at Hobart with the whole party by February, 1914.

A Status of Lord Kelvin will be unveiled at the University of Giagow on October 8th by the Lord Rector of the university, Mr. Birrell. The Kelvin memorial window in Westminster Abbey was unveiled on July 15th.

As Experimental Study of Vantilation Problems will be carried on for the next four years by a commission having at its disposal a fund of \$50,000, which is part of a gift made by Mrs. Elizaboth Milbank Anderson to the Association for Improving the Condition of the Poor. The chairman of the commission is Dr. Charles Edward A. Winshow of New York.

Radioactivity of the Atlantic and Pacific.—An Argentice scientist has made a series of fifty measurements of the radioactivity of the cosans, fifteen in the Atlantic, south of Montevideo, four in the Magellan Strate and thirty-one in the Pacific, south of Callzo. The radium emanation value, expressed m Mache units, was 0 14 for the Atlantic ocean; 0.09 for the Straits and 0.08 for the Pacific

A New Vegetable Ivery.—According to a consular report, M. Gaston Bonnier has submitted to the National Agricultural Society of Paris samples of a new vegetable ivory made from the ablumen of the fruit of a certain small palm, of the genus Hybanen, growing in the forests of the French Sudan. The product is said to resemble attempty that of the ordinary ivory-nut (Phystelephas macrocareps) of South America. The nut of the doom-palm (Hyphene thebales) has long been used for making rosaries and small ornaments.

used for inating reastres and amount ornaments.

A Cellege of Tropical Agriculture. The project of establishing a college of tropical sgriculture is being extensively agitated in Great Britain. The Board of Agriculture of Ceylon has appointed a London committee to accuse public interests in the question. At the annual meeting of the Ceylon Association, held in London June 12th, it was unanimously resolved that the association approved of Peradennya, Ceylon, as the best site for the proposed college. The famous Royal Botasile Gardens are situated at Peradennya, which is a suburb of Kandy

Gas in the Cartiles of Trees.—Prof. J. A. Ferguson, of the Pennsylvania State College, reports a currous phenomench connected with the cutting of hardwood trees in the Orark Mountains. Cartiles near the base of the trees are often found to contain gas. When these excited are cut into by the oak the cutters of the region the gas ecapse with a whisting sound, showing it to be under pressure, and if lighted it will burn with a faint yellow fame. The sides of the cavities containing gas are in all cases darkoned and look as though seared with a hot fron. The popular belief of the district is that these trees are connected through their nots with a test trees are connected through their nots with a tast trees are connected through their nots with a subternanean supply of natural gas, and the land on which they grow is valued accordingly. An examination of the gas collected from a cottonwood tree was made by Prof. Bashong, of the University of Kansas, and it was found to be substantially the same as natural gas with the addition of some free hydrogens. Prof. Ferguson believes, however, that this gas as the product of decomposition of the heartwood of the trees.

Steeping Tasi Veleane. With the aid of a special appropriation of \$9,000 from the colonial legislature, the Philippine Weather Buresu has established a seismological station on the shore of Lake Bombon or Tasi, about five miles frem the volcano that caused so much destruction in January, 1911. The building, wishis is of reinforced conserts, is situated about twenty feet above the level of the water, and thus commands a view of the lake and the volcano (the latter being on an island in the middle of the lake). The location is near the ridge of a fault which radiates from the volcano in a nearly southwest-northeast direction, and so expected to be very favorable for registering the alightest shoots having their origin in the volcano. The practical purpose of the institution is to obtain timely warning of, any impending ecuption and warn the inhabitants of the district. The station is equipped with meteorological instruments, a Vicentini microsimograph, and an Agamenones estimatorphy; also with a Fries water-stage register, a set of underground theremometers, for use on, the pland of the volcano, and two small deep-sea sounding thermometers for locating some of the subharenease steems were that are supposed to exist sevond the volcano, and two small deep-sea sounding thermometers for locating some of the subharenease at team wents that are supposed to exist sevond the volcano, and the original content of the subharenease at team wents that are supposed to exist sevond the volcano, and the proposed to exist sevond the volcano. A fine motor journel, easing the content of the such that the volcano is a supposed to exist sevond the volcano.

#### Aeronautics

German Military Dirigibles.—The German army has increased its supply of airships this year by eight, namely, four Zoppelins, two Panevals, one Schitte-Lanz and one arship of "M" type, making a total of thriteen dirigibles now at its disposition

Another Gyroscope Attachment for Flying Mackines.— Herbert E. Hawes, of New York, city, has patented, No. 1,067,425 a flying machine which includes means for inclining the balancing planes during their lateral displacements which include a gyroscope whose verticeal shaft is mounted on an oscillable bearing and means co-operating with the shaft so that the incretic of the gyroscope co-acting with a laterally tipping frame through suitable connections operates to incline the balancing planes.

Another Gyroscopic Stabilizer for Aeropianes.—A gyroscopic stabilizing devices is shown in patent No 1066,800, to dibinind Sparimann of Venna, Austra-Hingary. The patent presents in connection with other features coupled double gyroscopes which are able to effect symmetrical inovement relatively to the vehicle and also means for looking the gyroscope when the aeropiane is to be controlled by hand, as in ascending, descending or rounding a curve.

A Gyreacopic Controller for Flying Machine.—In a patent, No. 1,086,342; Edward D. Giren of Chicago presents a flying machine in which a gyreacopic wheel is rotatively mounted on an axis councident with the axis of the propeller with a run incircing the propeller. If an operation the motor breaks down or the propeller weases to revolve from any cause, the gyroscopic wheel, on account of its momentum, will continue to revolve independently of the propeller, thereby resisting any effort on the part of the machine to topplie over By changing the machine's course down, the momentum may be reacquired down, the momentum may be reacquired.

Three-dimensional Warfare. - in the two-dimensional rfare of the past the rear ranks have always been held in reserve. In the three-dimensional warfare of the future, when dirigibles and aeroplanes will be used, no part of an army will remain alle for any great length of time. If it is not actually used to attack it will be busily engaged in resisting attack. In that conflict of the future it is not unlikely that aeroplanes will be used in ways undreamed of now. If we cause a squadron of arcoplanes to fly low and thus convert them into a novel cavalry of unlimited speed and endurance, new possibilities dawn upon us. Because the machines fly in three dimensions, because they are speedier than horses, because they are numerous, they need not fly in rigorous formation. They can attack the enemy from any direction That agroplanes may become great fighters as well as great scouts is shown by the simple philosophy that the fighting power of mounted men rests in the strength of their horses. How can we contemplate the tremundous concentration of brute force in a 100 horse-power antoplane carrying two men and not conceive of aggressively employing this power? Travel swiftly and you are safe from fire no matpower? Travel swiftly and you are safe from fire ter how close it may be at hand. Rush past a r fle sixty miles an hour and he will not be able to hit you, although the distance be only a hundred feet. All that this implies is courage - the soldier's stock in trade—as well as skill enough to navigate the turbulent, swirling ground current, and a motor that will not fail at the crucial moment

Distinguishing Friend from Fee in the Air.—In time of war it would surely be difficult to determine the automaticy of an arcsplane flying at a great altitude. It as concivable that frondly arcraft might be bombaried and hostile machines allowed to escape. The sky is susually so lummous that a flying machine appears althouetted against it. Hence the device, used in the Balkans, of painting the outer ends of Greek, biplane wings and the vertical rudder with the national colors, blue and white, was not very successful Whatever identifying marks a machine may carry, must be large. Flags flown horizontally might answer, but even there, at great altitudes, must appear merely as appendages. Besides, if they are not to impede the machine, they must be very light. At great altitudes the nationality of an seroplane might be recognized not by the colors of its flag but by its distunctive design. In Morocco and in the Balkans the problem of distinguishing friend from foo in the sir did not arise, simply because in both campagns the use of arcraft was rather one-sided. The doubt whether a machine is a friend or not may cause the forces on the ground to lose the fow flowing monitors during which they have a chance of bringing down an air sount. Moreover, there are at present too many types. The same service types are to be found in several armos. Hence, it would be difficult, if not impossible, to recognize the instansity of a flying machine from its build, as sailors recognize a ship by the cut of her jib. It is far easier to telently airships chiefly because of their size. There is no possibility of mutaking a German Zeppelior for any other type of craft. With the Parseval type. The German "M" type is easily recognized, as so is the French Lebaudy.

at me mands of the workman who, by his own musclar power, presses the tool žirnly upon the work and magnitud a support. In sharing large lamp reflectors and similar objects in this manner, from thick disks of from, brass or cupper, the musclar effort required is so great that the workman must be strapped to the lathe. The most hand the strapped to the lathe. The work is very fatigulag and often causes cronic disenses of the liver and other organs, in addition to

discusse of the left hand, which the workman uses to hold a guide against the rim of the rotating disk to prevent excessive vibration. Articles that have bulged cannot be worked into shape because of the danof the operation. The process is o very slow and requires great skill

Hermann Rahn, a master mechanic of Heriba, has patented an apparatus free from the defects and dangers mentioned above. The essential feature of the device, as shown in the accompanying illustrations, is a pair of levers. One of these vers serves as a guide and a sumort for the tool to which it is attached, while the requisite pressure is applied by means of the second lever which can be operated independently of the first. In order to enable one operator to carry on the entire process alone, the rim of the rotating ob ject is guided by a roller and spring or some similar device, so that the left hand of the operator is left free to work the pressure lever.

In the simplest form of the apparatus the pressure lever is mounted on a pivot attached to the frame of the lathe, while sure lever by a universal joint, and can therefore be moved freely in any direc-tion. In a more complex form, adapted for a greater variety of work, the pres-aure lever is screwed into one of a series of holes in

the periphery of a disk which is mounted eccentrically on a fixed pivot, while the pivot of the tool lever is inserted in one of a series of holes in the face of the disk at varying distances from the center. By this arrangement the leverage and the pressure can be varied without affecting the guiding of the tool, which is free to be moved in any direction desired variations in the form of the apparatus are also available, but the principle remains the same.

Efficient operation of the Rahn spinning apparatus is so casily acquired that an abskilled workman, after two or three days of practice, can turn out more work can be accomplished in the old way by a Further workman who has had years of practice more, it is possible to work sheels of twice the maxi-

mum thickness used in the old proce num thickness used in the old process, and yet no straps or other devices need be used to increase the pressure. The average waste produced by unskilled workmen in the luproved process is said not to exceed two pieces per thousand, while heretofore the most skilled operators have counted on a waste of from ten to twenty pieces per hundred. One of the greatest advantages to the new pro cess, however, is the freedom from accldent and discuses to which the operators constantly exposed by the old method

#### Variable Speed Hydraulic Trans mission for Motor Trucks

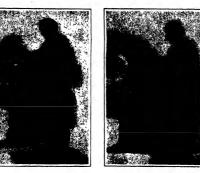

O NE of the most essential elements of the motor vehicle is the transmission system, for if this important part is not properly designed no end of trouble will result. The type of transmission most generally in use in both pleasure cars and motor trucks is the change gear set using spid genry. Of late years, however, the designer has been turning his attention to the development of other types of trans missions with the object of overcoming the inherent

disadvantages of the prevating spur gear Although the variable speed hydraulic transmission Ulustrated herewith, is not entirely new in principle it has been reduced in size and simplified in design for application to the motor truck. This transmission system consists of a reciprocating, multi-cylinder, rotating, single acting nump and two motors of much the same construction and operation, The pump is direct con nected with the engine shaft, while one motor is connected with each jack shaft. The pump and two motors are encased in an oll-tight, cast-iron housing as shown herewith. The working medium, by which the motors

are actuated by the pump, is a medium heavy machine oil. Besides the mechanical advantages of the hydrau-ild transmission system there is the added advantage of constant hibriestion of all moving parts.

The second se

own in the engraving, the main axis of the pump As shown in the engraving, the main axis of me pump harrel R is in the same line with the axis of the driv-ing engine shaft A, while the axis of each motor cylin-der C, stands at an angle of 45 degrees with that of its corresponding jack shaft D. The driving head R, which holds the piston rods, is rotated by means of a plate F keyed to the shaft of the engine. This plate is notched around its periphery to receive the piston The pump driving head E is so constructed that

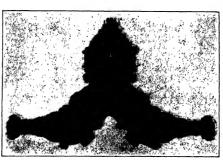

New method of shaping sheet metal objects by means of the Rahn lever apparatus. It can be done by an Old method of aninning sheet metal The operator must use the strap is order to obtain the necessary pres-

It rotates about an axis at an angle of 20 degrees, either side of the normal, with the axis of the driving shaft, This gives the driving head a total movement of 40 degree

On the other band each motor drive head  $\Omega$  is fast-oed to its corresponding jack shaft D. The fall stroke of the pump pistons H is shorter than the stroke of the motor pistons, and by regulating the angle of the driving head E, which is done by means of a land lever varied from zero to full stroke, while the stroke of the motors remains fixed. The pump cylinder burrel is keyed to the engine shaft, while that of each motor rotates on a fixed spindle, and is connected by means of a bevel gear J, to the jack shaft D

Speed variation may be obtained in two ways, each

The new hydraulic transmission with section of casing cut away to show struction of oil pump and motor,

method being independent of the other, while both are capable of simultaneous action. First, with the engine running at a constant speed, the speed of the vehicle may be varied from full reverse, through zero or neutral, to full speed ahead by changing the angle of the pump head E, by means of the hand lever, as explained above. This varies the stroke of the pump pistons, thus regulating the cylinder displacement. Second, the speed of the vehicle may be varied by maintaining the pump in any desired position and operating the fuel lever to regulate the quality of the explosive mixture passing to the engine cylind

The peculiar combination of the hydraulic pump and

motors gives somewhat the same artice, as a universal joint, inasmuch as it provides a positive reassection and rotation between two sharks operating at an angle with each other. Since the working fluid is practically as-compressible, if forms as positive a link between the sugino shark and the direting wheels of the vabilies as es the usual bevel gear differential.

One of the principal advantages of this up that it entirely eliminates the measurity of a closely that it entirely eliminates the measurity of a closely its attending weight and frequent trouble. Also braking may be accomplished by operating the lever, the necessity of two sets of friction was obviated. Throwing the lever to sets or neutral,

the vehicle against forward or backward travel. Herewith the complete species, is shown installed in a motor truck change. It will be noted that with this transfer site the cheases is recognitively securities, because in all mechanism inclous to obstone, which is crutial, brakes, and gruy gard 'grounds.' Although the pressure on the working study argue with the country of course.

fluid varies with the amount of power transmitted, and may reach 1,000 pounds per square inch under heavy service, the pressure may be reduced by increasing of the transmission system.

#### Action of Ultra-violet Light on Animal Organisms

GREEN plants are known to thrive particularly in red light which is ed by their chiorophyli, and water plants often adapt themselves to the greenish-blue light they receive, by assum-ing a red or yellow coloration. Blue and ultra-violet light does not exert a favor able action on green plauts, while be teria are injured and, in the event of a prolonged action, killed by these light rays (disinfecting power of light).

Many inferior animals perceive ultra-

violet light directly, being often disagree-

to carry their pupe from the light visible to man into the dark and to shun even the ultra-violet rays invisible

greater spectral range than man. Heat rays exert on the skin and mucous membranes effects different from light rays, the action of which lasts longer and may result in inflammations as well as excite the formation of pigments

In view of the conflicting views recently enunciated as to the action of ultra-violet rays on the retina and other media of the eye, Dr. Spuler, in a paper recently read before the Carlsruhe Scientific Society, considers the action of these rave on the animal organism. Abart from the solar spectrum, he examines organism. Apparets spectrograph the various sources of light in common use, ascertaining the absorption of various

glasses as well as the refractive media of the eye Open are and quarts mercury lamps were found, spart from the sun, to be the only sources of light giving out ultra-violet rays in any appreciable amounts. An ordinary thin glass plate will absorb a great part of the rays en uating from the sun, to which all those living much in the open air, are exposed; such persons, however, are known just to ossess especially good eyes.

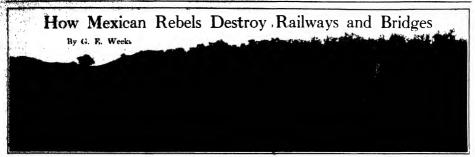

On the other hand, it should be remem-

bered that any strong source of light re-duced more or less to a single point will cause glare in the visible part of the spec trum, against which any glass affords some protection by absorbing part of these rays. The task of illuminating engineers therefore consists in providing a light similar to diffuse daylight such as (apart from the distribution of energy) is to found in indirect lighting.

Two New Foreign Institutes of Science

The executive committee of the German Society for the Encouragement of

Science and Industry, known as the Refer Wiffed Geschischaft, has recently decided to found a Hife dynamic and Aerodynamic Institute, as the Giftin University. It will be in charge, of Pays, Land Prandtl. At the last meeting of the Augustice, held June 17th and presided over by Frot Hars Emil Fischer was elected vice-president to a Prof. Ludwig Debrilds, receipt december note that the Coal Institute, founded at Mrs. note that the Cost Institute, required at minutes budget with be 120,000 marks, of which 150,000 marks are only tributed by industries established in the region of the 

Track pulled loose, wreckers piling up ties preparatory to burning.

THE deliberate destruction of railroad I tracks and costly steel bridges is a thing not often seen, but since the beginning of the Madero revolution in Mexico in 1910 such destruction of valuable property has been one of the favortie methods of warfare in that country adopted by those opposed to the existing government. This in due not alone to the desire to prevent the use of the roads for the transportation of troops and supplies, but also to the fact that the lines chosen for destruction are the property of the national government, or at all events a majority of the stock in those lines is the property of the stock in those lines is the property of the stock in those lines is the property of the nation. This is true of fully three fourths of the railroads is the Republic.

Many hundreds of miles of track have been destroyed, hundreds of bridges, many of them expensive steel structures, have been burned or dynamited, and it is said that over fitty per cent of the rolling stock of the national lines has also been wrecked, burned or otherwise put out of

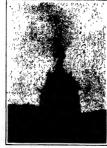

commission.

After Madero triumphed some effort was made to restore the destroyed lines and bridges, but rebel bands in various portions of the country made this a difficult task, and when in February last he was deposed and assassinated, there was a very large mileage which was still in need of restoration. As soon as Ruerta assumed power, the Maderiatas—now termed by themselves Constitutionalites, but by their enemies called rebelm—at once began destroying the railroads by which Federal troops could be moved against them, and at the present time there is a larger mileage of track out of commission than at any time during all the troubles of the past two and a little troubles of the past two and a little troubles of the past two and a little froubles.

or sae past two accession the writer had the On a recent occasion the writer had the privilege accorded him by the Constitutionalist leaders of visiting a point in the State of Coahulla, where track and bridge destruction was in full progress, and a most interesting sight it was. He was also permitted to carry a camera and take views of the work of ruin, some of which are given herewith. Up to the past aix months track destruction had been accomplished either by the use of a wrecking crane, which littled sections of rails and

This woman soldier travels on the train with the other guards.

Engine backing up and tearin

This shows how the 220-ton engine is shackled to the track, preparatory to pulling.

ties boilily and plied them up ready for intuiting, or by the slower process of the claw-bar, wrench and pleb. But a Constitutionalist expert devised a new system, which is shown in the accompanting photos, taken "on the spat" by the writer. A trench is dug between two ties, through which a heavy claim is passed.

A trench is dug between two thes, through which a heavy chain is passed around two opposite raths and made fast in the center of the track. To this one and of a heavy steel cable is hooked, the other end being made fast to the counting on the engine plot. At the signal the engineer starts his becommotives slowly backward, and as they are huge 220-ton "consolidations," with 22-inch by 39-then cylinders, one can readily imagine that something has to give. And if does." The raths are torn tone from the spikes that hold them to the ties and are dragged closely together in the center of the road-bed. The ties are tone tone from the spikes that hold them to the first and are dragged closely together in the center of the road-bed. The ties are tone some from the baliast and dragged into gibes, while in many cases the raths are badd, bett and twisted by the force applied. A raing of men follows the engine, pullus the out op of the man the case that the start of the spike of the substitute of the sum of the spike of the sum of the ground twisted and control data sints of shapes, and of no further use and the the case constitutes the tess re-translation and the spike of the second of the force of shapes, and of no further use and the second case the control of the same and the period of the second control of the ground twisted and control data sints of shapes, and of no further use and the second case of the second control of the same case of the second case of the same ca

An interesting feature to railroad men was noted in connection with the resistance offered by the fish and ite plates to the work of destruction. Where the old-fashioused fish plate was used, a single pall offered destroys from two to three kilometers of track before any resistance surficient to break the clusta is encountered. In this way as high as twenty kilometers of track have been tora my and burned in a single day. But where the fosibilite tiplates are used, as was the case with the track the writer saw destroyed, not more than one hundred to two hundred feet could be tora my at a time, the claim usually breaking in less than that distance owing to the immensely superior resisting quality of the fite-plate named. No better text of the comparative merits of the two methods of rail connection could be devised. The rails on this portion

The and-fact bridge at Salitage, mined in readiness for dynamiting.

Manager Caraman Cara Menanca and A.

Bridge at Obeyos burning after having been dynamited.

tion of the track were 85 pounds in weight and are stamped "Carnegle

The destruction of wooden bridges, of which hundreds have been ruined, is of course easy. They are simply saturated with oil and burned. With the steel bridges, however, it is different. These are destroyed by drillby boles into the piers and abutments close to the bridge seats, as also rows of holes horizontally along the bottoms of the piers where they can be reached. according to the state of the water in the stream These holes are charged with dynamite, the fuses are These holes are charged with dynamite, the fuses are connected with a battery of the type used in the coal nines in this region, and when the opportune moment arrives the electric current is turned on and the bridge is usually pretty effectually ruined. The accompanying ws a truss bridge at Obeyos, Conhulla, or line of the old Mexican International Railway, which was destroyed while the writer was at the place. This was merely displaced with dynamite and the woodwork ed. The solid steel girder bridge, five spans, over the Hermanas River, was destroyed a few days before the Ober & heldge, but it is so far within the enemy's lines that no photo is available. The solid stone masonry piers and abutments were completely destroyed, ng to eye-witnesses, leaving the girders bent and according to eye-witnesses, leaving the greens near and twisted at the bottom of the stream. The photo of the Sabinas bridge, also given, is that of one of the largest and most costly rallroad bridges in northern Mexico It consists of ten spans of solid steel girders, each 81.6 feet in length, carried on plers and abutments thirty feet above the water. This structure lies directly in the line of the advance of the Federals, and it has been prepared for instant destruction in the same manner ther bridges farther down the li

It will cost the national lines of Mexico many millions of dollars to replace their destroyed rolling stock, bridges, stations, etc., and this promises to cause them great financial embarrassment, if not bankruptcy, which at this time seems imminent. It will take years to put these roads in the same good condition which prevailed at the time Madero began his rebellion against Presi dent Diaz.

Pledras Negras, Conhuita, Mexico, August 29th, 1913

#### The Necessity of Accurate Railway Track Scales

With an almost unending discussion of ratiway freight rates, it is somewhat strange that tardy recognition has just been given by the Interstate Commerce Commission to an equally important factor in the problem. Prices and rates for commodities and their transportation are but one element in the equation of cost, for it is also essential to consider quantities Where the total amount of the changes is determined. not by numerical count of articles or packages, but by weighing, then the consumer or shipper is as much interested in the correctness of weight as in the selling price or the rate charged for its transportation. In words, an error of ten per cent in the scales is quite as important as an overcharge or rate ten per cent in excess of the proper figure. Indeed, it would seem most obvious that with a business undertaking so highly organized as an American rallway, freight should be weighed with the highest possible degree of accuracy.

Unfortunately such is not the case. We learn from a recent investigation by the Interstate Commerce Commission that three fourths of all the track scales In use in the United States are of defective design or improperly installed, that less than one fourth are properly inspected; that hardly ten per cent are proptested, not to speak of the great majority not being tested in any proper sense at all; and that nearly every-where methods of weighling are unsatisfactory and

This was the condition when the Interstate Comnerce Commission began its investigation in 1912, and such is the condition in large part to-day, though many of the rathways have realized their deficiencies and have undertaken reforms A few lines like the Penn-sylvania, Nanta Fc, and New York Central, which have paid some attention to track scale inspection for sev-eral years, have introduced improvements in design, eral years, have introduced improvements in design, impection and operation, organizing this work with technically that impectors. As most freight charges are computed to and lots by weight, insuling assessed by the hundre, the fit can be seen that the property of the contract of the c d lots by weight, nearly assessed by the hundre specific the supportant this inatter both the shipper and rating of the shipper as a general way officials claim or point due to inaccious the shipper as a general way of the shipper as a defense of present prepared or as an excussion of changing methods.

not changing methods.

In Minnesota and Oregon the Inspection of track scates is undefraken by the State Departments of Weights and Measures, and last January a bill with a

similar object was introduced into the Senate of the State of New York. In southern and western States shippers have formed weighing and inspe etton bureau to secure protection and advantages, but so far as the railways themselves are concerned, outside of a few lines conditions are generally quite bad, and there is lines conditions are generally quite bad, and there is great lack of uniformity. It goese cases care are weighed coupled at both ends, then coupled at one end, and then quite independently. Cars are weighed in motion as well as at rest. Mechanical and automatic recording devices are used in some cases. Not infra-questly weighmenters are carsiess and incompetent. The tare weights stouched on the cars it was found are in error in practically 80 per cent of American freight cars, and of 10,967 cars the figures were actuweighed correct in but 506 instances, and that the

error, which averaged about 500 pounds, ran up to 6,000 and 9,000 pounds in some cases.

While much can be done by the railways, the shippers and by local authorities, yet the Interstate Commerce Commission believes that some Federal commission, possibly the Interstate Commerce Commission, should be given authority to fix the points at which track scales should be installed, to prescribe standards track scales should be installed, to prescribe standars of construction, to test or supervise the testing, and finally to supervise operation. Failing proper local action this would be eminently desirable, but in the meantime much can be expected from what a number of the railways are doing to improve this department.

#### The Military Value of Low Flying By C. Dienstbach

THE real danger some for military aeroplanes in time of war lies at moderate heights. At great altitudes (4,000 feet and more) flying is reasonably safe A second zone of safety lies next to the ground; there, because a speedy aeroplane is most clusive and cannot be so easily hit as may be supposed. Spectators at fly-ing machine meets know how difficult it is to see a machine near the ground after the head has been turned for a moment. To a low-flying machine covers are as useful as they are to cavalry. But at a moderate hei an aeroplane can easily be tracked on its whole course, indeed, it draws the fire of massed infantry and artillery, consequently of a numerous percentage of highly skilled marksmen. Low flying, too, removes the seri culty of losing one's way, which often happens at high altitudes.

Because the aeroplane is not safe at these intermediate elevations, it follows that it must be able to change its attitude very quickly and easily. Safety will probable the desired supports and easily. ably lie in flying low until a safe distance is reached. whereupon an ascent may be attempted. With the attainment of automatic or semi-automatic stability in the near future it may confidently be expected that the aeroplane will become a practical, low-flying vehicle for war purposes at least. The aeroplane will then be like an automobile running on an ideal road which leads everywhere; or like a troop of cavalry which can gallop on untiring mounts across rivers, fences, ditches, trees, with three times the speed of the finest race

The low-flying aeroplane is concealed not only behind hills, woods, and villages, but also in front of them. The sky is the worst possible background for aircraft, son-Fulton trophy in 1910, Curtiss was completely lost from sight while flying below the top of th

Bomb-dropping obviously becomes more effective the lower the altitude of the machine. A squadron of seroplanes flying very low, could suddenly attack a fighting front from the flank and drop bomb after bomb Each machine while rushing along the entire liz would merely drop bombs in its tracks. A miss would be difficult. To be sure, a certain distance would neces-sarily separate a leading from a following machine, not only because of the explostves, but because of the danger that lurks in the invisible wash of propellers. Under the same condition machine-gun fire would prob-ably prove even more efficient, because lighter, and therefore a greater quantity of ammunition could be

But before the low-flying aeroplane can really p But before the low-drying scroplane can really per-form the function for which it is manifesty destined it must be protected. The vitals of an scroplane are much smaller in volume than those of a horse. Hence they can be even more easily protected by armor with out cutting down speed or modility than were the chargers of medieval anights. Already the military s of the world demand protected machines. the war of the future we may therefore expect to see steering gears, motors, and men all incased in bullst proof steel sheeting

#### The Two-speed Rear Axle

IN the Screntific American for August 2nd, in an Agricle on a new two-speed rear axie, it was stated that "the car will travel nine miles farther on a given

amount of fuel with the hi with the low gear in use." Manhactly, this is and the statement should have been The travel nine miles farther on a given number revolutions (700 revolutions a minute for with the high gear in use than it will with the

THE International Congress of Medicles, repent.

Theid in London, brought many remarkable countributions. We reproduce here from the Devices Them (Weekly Edition) brief notes on two or there of the most startling new advances placed on record.

#### Removal of a Lung.

The Section of Surgery discussed is new breasts of surgery, "Intro-thoracte Surgery."

Sir William MacEwen's contribution to the departs was by far the most interesting and inferential of the subject. In the first place, he wished to demonstrate a patient operated on by him 18 years sage, whose left long had been removed in its entirety for tubervulai disease. The patient had been brought from Glasgow and was seen by the section to be a ground. disease. The patient had been brought from Glasgow and was seen by the section to be a strong, healthy-looking man whose left side was hollow and fallen in. He was engaged steadily at work. At the time of the operation the right inng was diseased, but the removal of the hopelessly diseased bung was followed by im-provement in the condition of the reseathing inng.

provement in the conduction of the remaining lung.

That experience had been found in four other similar cases. In all these cases the spex of the diseased lung had been adherent to the great refl at the root of the neck, and at a later stage in the last four cases the vein and that piece of lung were removed. In the first case and that piece of lung were removed. In the lire case the patient for some days suffered great distress from the "dopping" of his heart to and fro as his position was changed. This symptom was obviated by stitching the pericardium to the front part of the chest wall.

#### An Artificial Kidney.

nonstration which excited great interthat of Prof. Abel of Baltimore.

Prof. Abel presented a new and ingenious meth removing substances from the circulating blood, which can hardly fall to be of benefit in the study of some of the most complex problems. By means of a glass tube tied into a main artery of an anæsthetised animal the blood is conducted through numerous celloidin tubes before being returned to the veins through a second glass tube. The celloidin tubes are immersed in saline solution. All diffusible substances circulating in the blood pass through the intervening layer of celloidin, and can be found in the saline solution, where they can bjected to fractional analysis. In this way Prof. Abel has constructed what is practically an artificial kidney. In many instances the working of the added excretory organ is more rapid than that of the actual kidney of the animal; 3 per cent per hour of salicylic acid can be removed from the blood. Although primarily the apparatus is of use in the estimation and analysis of the diffusible contents of the blood, it is bossible that the principle may ultimately be adopted in the treatment of disease. At the close of the demon-stration, which excited the liveliest interest and discussion, Prof. Abel was accorded round after round of ap

#### Transplantation of the Kidney

Dr. Ernst Jeger demonstrated a number of specimens to show what had been achieved experimentally in dogs. He had successfully removed a place of artery and its nat successfully removed a passe or artery as a stitched in its place a piece of vein taken from the same animal. He had transplanted one kidney of a dog from its abdominal position to the neck, joining the reasi artery to the carotid artery, the renal vein to the jugular vein, and the function of that kidney was co

#### Prototype of the Yale Lock

Prototype of the Vale Lock

O'IR attention has been called to the fact that in a contributed article in the Scurryinc Assumand for August 16th, 1913, on page 125, entitled "Prototype of the Nais Lock" the word "Yale" is possibly goed in a descriptive sense, referring to the particular type of lock. Of course, if the word is so understood in the article such use is inaccurate. The word "Rale" is connection with locks has been for many pains the recognized and established trade mark of the Yale is Towne Manufacturing Company, and it must be designated and established trade mark of the Yale is Towne Manufacturing to Company, and it must be designated and call the particle of the Yale is Towne Manufacturing to Company, and the use to designate the particle of the Yale is the Yale Locks" as the cythoder loop Illustrated and the Article referred to the well "Rale" and and the Article referred to the well "Rale" and and the Article referred to the well "Rale" and and the Article referred to the well "Rale" and and the Article referred to the well "Rale" and and "Yale" is concerning to the content, or chat collegation for market the Article referred to the fact collegation for market the Article referred to the fact collegation for market the Article is concerning to that contents.

Brookiya, N. Y. GEORGE FOSTER HOWELL

#### The Maximum Parcel Post Package

To the Editor of the Scientific American:

Mr. Taylor's communication, published in your number of July 19th, page 51, on "The Maximum Parcel," is very interesting and highly ingenious. Allow races, is very interesting and highly ingenious. Allow me to observe, however, that no person has any serious doubts as to what is meant by length, although some may evidently differ as to the proper wording of a defi-nition for the term.

The definition of length as "the greatest distance in gittaight line between the two ends of the parcel" got as faulty as Mr. Taylor makes it appear. The and to the state of the season of the season of the season of my rectangular receptacle, for instance, are two, parallel planes and these are equidistant at all points, so that distance between the "two ends" cannot mean distance between two of the "eight corners," selegibled so as to measure at an inclination to the "length"

speak matesize everys, but materials are simpled as as to measure at an inclination to the "length" dimession of the package.

The belvious reason for saving "greatest distance in a straight line" is to cover irregular packages, having no well defined dimessions, and to prevent too long a measurement by bending of the string or tape.

As I construct the rules of measurement, the length and the property of the construction of the string or tape.

of a parcel, however irregular such parcel may be, is equal to "the length of the smallest circumscribed rectangular parallelopipedon." but this would be a reconsiguiar parameters of the transfer of the dangerous definition to use as some of our well fed country postmasters are subject to apoplexy, and you will find that it is difficult to say the equivalent of this school room definition in a few simple words.

Arlington, Va. JOSEPH BECKES.

#### Progress in Air Navigation

To the Editor of the Scientific American: Several recent visits to Hempstand Plains have confirmed a previous feeling of disappointment, that the art of flying is still in the amateur, or bloyde state. The automobile stage or precious application of the genetic discovery seems not only not in night, but not great suggested.

with suggested.

Langley's experiments (Simithsonian contributions, 1891-1893), showed that he had solved the problem except for three elements, all of which have since heen supplied. First, a lighter and more powerful engine. Second, a method of safely leaving the ground and slighting. Third, a method of controlling the course of the aeroplane. (See Hiram Maxim, Century Magazant Lance)

slighting. Third, a method of controlling the course of the aeroplane. (See Hiram Maxim, Contary Magazine, almany, 1980).
Three things strike the observer, on examining the insect mobilines now shown to the public.
I. Sisceiting the engines by twriting the propolars. This 'cortainty assume primitives. Imagine it done raided fee is waterard.

This insteading of the wings by when, wire cords, and fig. signific of steel. These are factored of the by imagine of steel. These are factored of the results of the contained fig. and the contained of the second of the steel of the contained of the second of the contained of the second of the contained of the second of the seco

A. The searther over rough ground must set up a man an the wires and basessings. It seems the arresme

of careless management to subject all these slight bits of steel to the harring and delling sessed by the great levesage of the long outlying places and allerons. A large space like a draw field, could be planked over, and the stage and landing shade with much greater

smoothness.

The wooderful case and grace of the planes, once in the air; the speed, guidance and control; the floating and glitting extent to the ground; all these prove that the main difficulties were solved two or three years ago. Since that time, there has been little gain, as far as can be seen, in the directions of wider use or greater

salety.

A model was shown has wishing its a Breadway window,
of a placform lung beneath, see the state of the context of gravity lowestics, and a parametry hold a new of eight or ten. The presentes stated that it would come to the granted in salety, on the practical three is a suggestion of the state of the salety of the

The progress that has been made in aerodynamics during the last two years has not been journalistically sensational. Hence, is not so widely known as it ought to be. Engine powers on the whole have been reduced and speeds have increased, proof enough that the problem of air resistance and of securing stream-line forms has not been neglected. Eiffel's experiments, painstakingly conducted, for many years, but unheralded in the daily press, have disproved much of what was regarded as aeroplane gospel three years ago, and have enabled seroplane designers to work more intelligently. Even some of Langley's work may be regarded as superseded by that of Eiffel.

supersected by that of Eiffel.

As for the minor points to which our correspondent calls attention, we might mention that more or less successful attempts have already been made to start aeroplane engines with cranks; that the wire fastening of the wings is not regarded by designers as the best method of stiffening a wing; and that some designers,

method of something a wing; and that some designors, notably Gallaudet, have very ably solved the problem of holding wings by other means. The difficulty of starting over rough ground is not likely to be overcome by the means proposed. If a large space "like a dance hall," carefully planked over, is to be the chief reliance of the acroplane in starting, why not recur at once to the old Wright starting rail, why not recur at once to the old Wright starting rail, which is much simpler and cheaper? The truth is that an aeroplane must be designed to withstand the rack-ing strains set up by bowling over rough ground at high speed. Dance hall platforms could never be ubiquitous. Indeed, the French military authorities realize this, and even require machines to run over freshly plowed fields and stubble. It is easier to adapt the machine to the ground than the ground to the

#### Teaching the Tropics How to Live

To the Editor of the SCIENTIFIC AMBRICAN:

In the issue of November 9th, 1912, of the SCIENTIFIC AMERICAN, we find a description in concise form of the application and maintenance of hygienic conditions in the Panama Canal district, to combat malaria, the greatset enemy of the white man in many tropical, sub-tropical, and some northern districts. But for these precautions and their results, it would have been far more difficult to achieve so great a success in time as was the case with the great Panama Canal.

The afore-mentioned article clearly shows that such

neesures involve an extremely large exponditure. The statistics were derived from results obtained with only a part of the workmen employed on the canal, as some men, were not made subject to these measures and others were beyond control because they oured themselves when stricken.

e improved hygienic conditions tend to increase the number of working days, consequently a considerable sum of the working appears is saved, the wages being very high. The sum expended on hygiene will be cov-ered by the extra labor gained and the resulting increased

Persons who have been employed in the tropics under Persons who have been employed in the trypics unner quite different derounstances, for instance, in work on a smaller scale, with limited working capital, lower wages, and remote situation, are inclined to think that the costly method of conducting malaria hygiene is inappli-

costly method of conducting malaria hygiene is inapplicable in the vege transporty of cases.

I therefore want to point out in this letter how, on the Guinan place in Dutoh, Guinan, a notions malaria dissipita at 120 kijoineters from the coast, a really good result was obtained with year, duple guess and little ottilay, but without broughtlatels medicaments. This result was abcomplished with 120 to 18 Europeans of pure European descent, solet of whom came directly from European descent, solet of whom came directly from European descent, solet of whom came directly from the sealered a great deal from malaria previous to their coming under the protection of these hygienic measures, was steadily improving, although residivirus were still

essionally absent through Illness, especially when the bot season had must set in.

For several years malaria has no longer been dreaded by Europeans on this placer, as there were no reports

by Europeans on this piecer, as there were no reports of absence through malaris in all this time.

A dotailed description of these measures is contained any book, "B Brief Outline of the Surinam Gold Industry, Geology, Technique, Hygiene," De Bussy, Amsterdam, 1911 (English edition).

It will suffice to state here that I started upon the le that in a country where the hygienic conditions are entirely different from those of a civilized European country, the mode of hving should likewise be altered

or, and not in some details only.

application and maintenance of hygienic condie applicati tions is not so difficult in itself, but the fact that it extends over a number of people, many of whom are care-less by nature, does not facilitate matters. One has to exert will power, not only upon himself, but over others as well, and this in a popular manner.

For medical and practical reasons, chemical prophy-laxis is not suitable for a prolonged readence. In this instance the so-called mechanical prophylaxis is applied.

the results of which are pronounced to be ideal.

Our precautions did not extend beyond the actual dwelling place, because the surroundings were exceedingly unfavorable for malaria hygiene. Owing to numerous swamps (drowned forest ground) and work pits, drainage or constant supervision would either have become very expensive or would have been altogether in-sufficient. A removal of the whole hody of workmen and their dwellings to a more favorable situation at Savannali, some 5 kilometers distant, would have been savaman, some of knometers unusur, would have peen both expensive and impracticable, because of the great distance of the places where they have to work. Only the insmediate vicinity was kept clean and in good conditlon

The houses were built in such a way that they wer ermanently airy; the light could come in freely, and the whole building was kept practically anophele free Domestle work of any kind was done under ganze protection. The beds were provided with curtains of a special construction, which guaranteed the sleeper absohave been indoors. The houses were connected with each other by means of a long passage, likewise provided with

Suppor was taken at six o'clock instead of at half past After sunset few wished to leave these airy homes, although a pleasant recreation hall within safe reach drow many of the people to intercourse on account of the billiard and reading tables. The work-place was lighted by strong lights in case of night work, the surgood grants in case of night work, the roundings were cleaned, and rost was taken in anophine apartments.

Another successful measure was based on the principle that the staff should have a certain interest in the strict upholding of the simple hygienic laws and the proper keeping of the hygienic arrangements. This was done by the superiors, who set the example by giving the staff instructions about the causes of illness and how to com-bat disease Also a special wage system was introduced This system was based on the principle that every good and careful workman is enabled to earn a very good wage, whereas in the case of malaria or sexual diseases the men had free nursing, but were paid only a small part of their ordinary wage, in the case of any other illpart of their ordinary wage, in the case of any other in-ness they received botter pay. Then there was a premium paid for anopheles specimens caught indoors. The result was that everybody watched the results with the greatest

The cost of our malaria hygione amounted to the sum The cost of our materia nygione amounted to the sum paid in the shape of surplus wages and salaries—in real-ity nothing but a health premium—and the expenditure for the installation of the gains walls, windows, and doors of the buildings. Metheal attendance for malaria cost us next to nothing.

By laying down these rules, work on the Guiana placer was continued undisturbed. The adapted mode of living and the facts that the hygienic conditions and the sases prevailing in the country are generally known. and that the whole of the staff was made responsible for the proper order of affairs on the placer, combined to ereate for our men more agreeable work, and the company reaped the benefits of steady, undisturbed work.

HB amount of data constituting the sum total of in-This amount or date community being grown at a truly marrelous rate; The scope of libits; has been extended over theoretic of years for evolvaluelest broadlession of Egypt, Batyles, and Assyris, purily into the very details of dally life while the local extent of blaterical research has leen searly doubled, the whole of Asia (India, China, Japan), America and Oceania, having been added, with their most at cleat as well as recent lifetury, harizalte of the patitical aper teens, languages, literatures, aris and folklore of their labeld tants. In the realm of natural science (motogy and botany), thousands of extinct species us revealed by paleoutiday; re been added to thousands of calsting species, and the fi ing organisms known to man have grown energousit through addition, by the microscope, of further theusends of infin itely small beliage so far facishie. Not has the number of ercress daily teorgist to light or that of ete facts with the increasing discoveries of new elements and combinations of old ones increased at a less stapendons rate. Pro cress has been made in all fields of human knowledge, and new nces are first springing up. The mass of our kn weighing heavily men as, accumulated facts are describing of air and light and hungering our free d Became of the energoes amount of knowledge to be abserted the youth of our colleges is fast looking the faculty of atilisin the knowledge thus acquired. Nearly half the life is used in to petitus ready for life. In a recent paper, I'v. M. Golibo

suggests a principle which would seem plone to allow men knowledge to be classified for treaty reference, thus doing away with any need for a stortle exertic of memory. The lifes, his a sense, is already corried an to an American lose-leaf encyclopedia, the politicher of which supply new pages to take the place of those that pro obsoirle the Guidatein's principle inflords a means of reconling all facts at present known as said as those to be discovered in fature, with the same safe ty and once us though they were registered in our mem cey, by providing a material correctionedly, have ly kept aterest of the state of hinem knowledge Scientific education thro would consist, in future, much from Importing a knowledge of the outlines of a given science or doctrino, of irrediting how to use this curred partie and how to add to its (resource by personal work. It will be a question of audenticother and knowing "how to do things," rather than knowing a most of Individual, often allocamented and moires fact Kalethy encyclopedias are ecidently imagened in their bookist starmeter, and are descend to become antiquated by the time they are completed. The conof a book are necessarily humorable and any thus in contradiction with 185 which is morable, in inand flow. Books are well adopted for recording a finished system, exposing an established ductrine or life etary week. In the case of a mere storehome of facts, the infinitely more mobile form of the card old however be subplied, possibly, we might sold to the culbur's suggestion in conjunction with Dr. Gold d's Mercebolographie Library system

A Bibliographic Center would have to be created which would be kept abreast of any vactation in the actual status of farmen knowledge by permanent collab orators chosen among the connectent reco ruch brasch

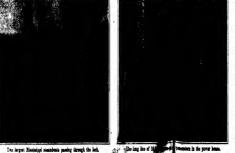

This Central Institute would have to prepare from the information thus received, periodical supplement and recification cards to be sent out to subscribers as given intervals, in addition to or in the piece of their old Information cards

This nexel exceptionally would prove other thene show the advantage of renewing libert periodically, like a human organism, and of never becoming antiquated A glance at the newly-received index curds would keep Ividual investigators permanently admost of all the is being done in their tropestive fields. The encyclepedia would serve on one hand as a reference work ensiding anybody to nequire the most exhaustive in s desired on a given subject, more supply and completely than by means of any existing tool. On the other hand, it would give of each schene or doctrize in its whole or any of the parts, a system line so that even those unequalited with the healing facts might be able to oldala beforments

The suggested encyclopodia would of course nilow of any subdivision, so that only the large libraries and State institutes would have to obtain the whole work, subscribing to the whole information service, individunia being content while the weilors of special importance for their own needs

#### Military Aviation in Italy

E learn that the Italian experience has entered 10 aeropianes with a view of giring rapital innce to this amendon. It is stated that all of the will be constructed in links, the greater part of securio of the Memori, Rivid, Forman and Brisio fras. Of this last make their are along 30 marbiture ordered. A good number of the above muchilies on already in construction. The military commission received 14 normpleanes not long since, and the coming army concerne is to furnish about 19 more Contha all the above, the aerophus feet in itsh will som be increased by 130 units, and at the same time the governefament is taking steps to secure all the power wators and other material for making up the arms aeropian sections, each of which is to inve-6 aeropianes. No doubt the serotions sections or compa will be organ last after the pian which proved so successful in France, that is each of the 6 necessaries has one process wagen to earry the naterial, stores and space parts and this tows a trailer can reminishing the acresions Headed by the officer's cut, this makes a travelling camp which is set up to the open air or travels over the road, accompanied also by special reputs shop cars Turin has been chosen as the leading aviation center both for practical and scientific work, but the arms also arge acrodicanes at Mirafleri. Veneria Resile and St. Maurice. The Royal Industrial Number has just nited a mader of avlation inhomorphy which will be used for teeling of motion, prodyments work and like, and all the offeres of the presentle corps will take part in these operations. Accordings for the army are purchased out of the credit social in Purifiment or with the sums raised by national andand the Aero Club of Italy has charge of some of these latter expenditures. On the whole it will be seen th accopians matters are very active to that country

#### Machine Cut Herring-Bone Gear

Title advance which has now been made in the way of producing double ber-ring-hane gear wheels for all kinds of industrial use is well illustrated by the remarkable specimen presented herewith, and it is also an example of the way in which gear manufacturing is becoming-specialized. The factory where the gear made has gear-cutting machine stalled for cutting herring-bone gears upon wheels up to 30 feet in diameter, and rolling mill pinlons of as much as ten feet in length Within a recent period the advantages of this class of gearing have become more and more appreciated, not only for use in rolling mills to transmit the large amount of power needed for the rolls and at the same time be able to stand the very severe shocks arising in this kind of rk, but also in the navy and other fields where the use of electric motors is now becoming general. This kind of gearing is in fact well adapted to work in a numher of cases where a large amount of power is to be taken from an electric n tor. In view of the increasing demand for the gearing, the factory above referred producing herring-hone gears, and owl to the specialization of this work, it is no to the specialization of this work, it is now turning out gears of high quality and precision. In consequence, the French navy is now making use of these gears largely. They are used upon a number of the battleships of the fleet for driving some of the muchinery on board, for in-stance the "Taris." "Lorraine," "France" and others. They are also used on board four hattleships of the "Verite" class and also on two crulsers for the machines of the rudders. For this same purpose they now applied on submarines such a "Emeraude" with great success are also employed in the Transvaul mines where 31 gear sets serve for electric winches of 250 to 600 horse-power, and 23 are used for tube mills

#### "Baboon Face"

THE photograph berewith reproduced shows a portion of a log of dogwood (cornus fordia) which counts in a peculiar growth. One might suppose that it represented a crude attempt at a carring of the face of sin ape. But the specimen is a natural reask and its represented just as it grew on the tree; without the help of the tool. Such formations are not un-common and are known by lumbermen as "huboon face." The particular specimen here shown is unusually striking. It was cut from a tree in Mississiph.

#### Novel Colorado Hydroduct

THE accompanying illustration shows a novel sheet metal hydroduct over the main line of the Chicago, Hurlinston and Quincy Rallinoud, near Keenburg, Colo. The diameter of the finme is 7 feet and the height above the ratil is 20 feet. Constructional details are shown in the line drawings which are longitudinal sections at a Joint. The expansion Joint used is as simple in construction as the regular wedged Joint between sections. It has no rivets nor solder, is efficient, easily exceeded and requires no more room between stringers than that provided for the waterway.

The two meeting eads A and B are bent to form groves which are nosted one within the other. A bar C, shaped to fit the curve of the hydroduct, is received to receive the grooved eads A and B, then a wedge D also curved to fit the semi-circular hydroduct is driven into the groove fastening the eads A and B to getter providing a smooth floor for the water to flow over. The metal sheets are wedged and not simply "clamped" between the Johnt bars, and the weight of water carried by the metal sheets, is supported on each side of the Johnt by the wings of the bar C, to the public where the sheets are bent downward. The wings are sheared from each end of the bar C, teaving a round section which is brassied and when the muta are drawn tight on each end, the wedges are 10 a forced on the carried when the muta are drawn tight on each end, the wedges are 10 a forced down

duced by the plate, and stamps get, esperaspouding farror on the plate. While atthems the sorting to, be checked at any mouself, More than 19,000 plates can be, sevedap per day without any excessive strain. In order further to facilitate the work, the machine, unlike the arrangement represented in the accompanying fayrre, is mounted on a small rolling bench or which the workman travels along from heap to beap.

#### Machine for Swaging Automobile Wire-wheel Spokes

A MACHINE that will take wire from the coli, straighten it, form it into apokes, avaging the spokes between butter and mechanically cutting them off to lengths after awaging, is depicted herewith. The coll is aboven in the extreme left of the engraving, and passes through a straightener of the rotary wheel type. It has office steel eyesles mounted with ball bearings in suitable holders and bearing yieldingly and revolubly against the passing wire so that there is an marring of the surface. The wire from the straightener enters the swaging machine through a hollow spindle fitted with disc. These dies close automatically over the wire after allowing the portion forming the butt to pass out of them, when they impact in another of sharp clean-blog-simultaneously from diametriscity opposition of the section reducing the stock rapidly and, girling it a sort of "hammer femper." The dies then open gain astematically, allowing the portion of wire forming the opposition butter to pass out of the machine proposition of the machine head and draws the wire through. By means of the varied due spokes, in the varied tors poshes of different size. The varied tors spokes of different size. The wire rational strains of the strains, so the strains of the

This system of fire protection has an inherent defect. It is neces sary for the fire fighting apparatus

ance to the fire after the detection of the blaze and the delay occusioned by finding a fire alarm box and operating the same Even theu, after the fire apparatus hus arrived at the box, it is necessary the exact location of the tire and to conect the apparatus to the nearest hydraut Although the modern fire departments are remarkably well orgunized and the men are carefully trained to do all the neces sary work in a surprisingly short time, still it is a fact that this system has a disadvantage of losing the first few mlp ites of time when the fire is just starting, and when it could most easily be quenched. To ald in determining the exact location of fire the electric enunciaor has been very widely installed. This is an arrangement for indicating at a central point the hullding or the room lu which the fire has started

In fact, as early as July 25th, 1846, a patent was issued to an inventor by the name of Addison Smith of Perrysburg The diagram shown in Fig. 2 1. a sketch of the circuit employed, and at ough the latter is remarkably simple it is as complete as many of the modern lustallations. The patent exhibits a very efficient form of thermostni which is shown diagrammatically in Fig 3 brass cylinders made nir-tight are con nected to it tubes which are partially filled with mercury in the nature of the well known air thermometer. The right hand cylinder baving very thin walls heats quickly, and the air expands, forcing the nercury up to close the contact at the point "A," whenever the room is heated quickly as by fire. The other cylinder has thick walls and heats slowly, and in case of a general dangerous rise in tempera-ture the contact at "P" is closed and the ularm "X" is rung and the appropriate drop is exhibited. Substantially the same scheme is widely in use to-day.

In about 1875, another important step

was made to overcome the defects of the central fire station system. The so called sprinkler system was invented. In this system, water pipes are run along the ceiling of the rooms of the building to be protected and about every six or feet apart an outlet in the form of a spray rect apart in outter in the form of a sprint mozzle is provided. This nozzle is closed or shut off by means of a fuelthe plug usually nn alloy of metals. The plug melis at about a hundred and sixty degrees The water in the pipes being con-stantly under pressure, is forced out and sprays or sprinkles the space below it for in area of about 40 square feet the usual space supposed to be protected by each nozzle. This system, when prop-erly installed is claimed to be very effi cleut, and it is stated on reliable authority that about ninety per cent of fires orig hating in buildings protected by sprink lers are automatically extinguished How ever, this figure is very misleading. The grent difficulty is to keep in suitable working condition the complicated system of pipes and valves. There is constant danger of leakage or tumpering with the plipes by unauthorized persons. In event of an actual fire unless someone is at hand to simt off the flow of water, the sprink-lers will continue to flood the building So, although the fire is put out the dam age from water becomes excee The cost of such systems is very high

It is estimated that the average cost per sprinkler, including the necessary piping, valves, and sprinklers, is about \$30 to \$40 This is exclusive of any meter equipment or siarm devices. This high cost is par-tially accounted for by the utilitude which the management of water companies evince toward such installation. It is a peculiar fact that a regular charge of from \$25 to

(Concluded on page \$17.)

Mastric system fire slarm station

THIS U-S-L Electric Starter shows correct application of a correct

of the automobile engine while the "armsture" is bolted to the crank-shaft in place of the engine's fly wheel. With the turning on of electric course,

in place of the engine's fly wheel. With the turning on of electric current, the "armature" revolves and thus starts the engine.

There is no "connecting lever" to throw, because the U-S-L Electric Starter is built as an integral part of the engine, direct-ensemented.

As there are no gears—and only the "armature" moves—the U-S-L Electric Starter is nouseless. As the "armature" is the only part of the starter that moves—and as it utilizes the crank-shaft bearings—there is nothing about the U-S-L Electric Starter to need oiling. The only points of frictional contact are where the "brushes" meet the "commutator" and these "brushes" are, of course, "self-lubricating.

Being especially adapted to—and built for—each type of engine to which it is attached, the U-S-L Electric Starter is always amply provided with power. It will "spin" the stiffest engine, turning it over at from 150 to 400 revolutions per minuse.

with power. It will "spin" the stiffes to 400 revolutions per mitute. When the engine attain's certain speed to 15-1. Electric Starte becomes a generator of electric current. It then recharges the battery for further earning and also provides your cut with light. Some street for further earning and also provides your cut with light to 15-1. Electric Starter, Some or later you will decide to buy only case equipped with this starter—furt, because it is infalling—strend, because of the simplicity—this, because it no moletan—faurth, because of its lightness—and swowth, because of the simplicity—this because of the simplicity because of economy.

#### Electrical Fire Protection (Concluded from page 215)

\$50 is demanded of every four-lack cor on made to the city mains. This is exclusive of the meter rent, which the owner is also forced to pay. Now the man who installs the most efficient form charge merely for being connected to the city mains. The owner of a building with out such protection is not required to pay our such protection is not required to pay any charge whatsoever, but can demand the installation of fire hydrants at his very door. Yet in the case of fire no charge is made for any amount of water required to be thrown upon his building, and such quantity of water is very much greater than would be required to extin guish the same fire by means of the auto-matic sprinkler. So in the case of a maowning, say, a \$100,000 factory or building who has expended about \$20,000 to ade quately protect the same, a charge for every drop of water used is made. The ovident man, disregarding the safety of the community about him, is charge absolutely nothing for the water that may sary to extinguish the fire in hi bullding.

The lustaliation of such protection ma terially reduces insurance rates, but I often gives a false sense of security and the owner will reduce the amount of insurance carried. An incident illustrative of this condition occurred in New York city. An owner who boested of his complete protective system, which consisted of four connections to the street main, were nformed by an inspect these connections were found closed, and, in fact, the valves to the mains had no

Happily the aid of the electric current as been secured to furnish a better pro has been secured to furnish a better pro-tection in the matter of such installations. Instead of having the pipes constantly full of water, and thus exposed to the danger of freezing and corroding, thermostats are placed throughout the protected area, and upon a dangerous rise of the temperature the valves are electrically opened and upon cessation of the blaze they are again closed automatically. By this means flooding is prevented. Electrical contacts are placed at every valve to prevent tampering with the device, and in case of unauthorized cleaures of such valves an alarm is rung at a central point. By means of such improvements a more

adequate protection is secured, but the prohibitive cost renders imperative cheaper means of securing the same ends Future developments along the lines of less cost will show an increased use of the thermostat and other electrical devices which have in the past shown themselves to be the most reliable and efficient means for securing fire protection.

### The Current Supplement

I N a paper read before the Rallway Club of Pittsburgh, Mr. G. E. Ryder deals with the maintenance and operation of superheater locomotives, showing how, by proper attention to certain points in con-struction and operation, this type of loco-motive effects economies over the type em-ploying saturated steam.—Prof. C. J. Tilden's paper on the Kinetic Effects of Crowds is a contribution on a subject to which hitherto only occasional and passing attention had been given, namely, the effect of movements of individuals crowd, upon structures such as bridges grandstands, etc., occupied by them.—1)r.
A. Maverick, in an article entitled "Blun-A. marerick, in an article entitled "stun-ders Made by Nature," shows how the human body, so far from being perfectly adapted to its environment, has a number of natural features that positively invite sease.—A combination of the Ostwald ocess for making nitric acid from ammenia with the manufacture of calcium cyanamide is described.—H. W. Perry writes on Permanent Roads as an Beon omic Necessity.—The third instalment of Lieutenant Colonel J. E. Kuba's article Lestemant Colones J. E. Kunk's arrive on reamportation deals with ocean traf-fa. M. Lesteman reports on an analysis of the place from pages, c phenomenon to the place from pages, c phenomenon

### This American Adder

### Goes on 150 New Desks Daily

Here is an innovation hardly six months old. A perfect adding machine for only \$35-rapid, full-size and infallible.

A machine which adds, subtracts and multiplies-computes a hundred figures a minute. Which anyone can operate-which never makes mistakes.

A simple machine which outdoes the complicated. low-priced machine which does the work of the costly.

The machine was so welcome, so widely-wanted, that the sale has jumped to 150 per day. It is now the most popular adding machine in America.

### Note the Advantages

The price is so low that every desk may have its individual Adder

Instead of the central machine. for which workers must wait, you have at the same cost a number of

No expert is needed. Ea worker makes his own additions.

The American is also a portable Adder, weighing but 17 pounds. No need of carrying books and papers. Place the machine where they are.

### **Small Offices**

Competent adders have hereto-fore cost \$150 minimum. Now comes a machine at \$35 which does all that they do, quickly and accurately.

These machines by the thousands are going to factories, shops, offices and stores which have never afford-ed an adder. They are saving labor, prohibiting mistakes.

A million men will have this Adder when they find it out.

### Accuracy

There are only seven keys. The figures are clear. Copying mistakes are improbable.

But each complete number, be-But each complete number, be-fore the addition, shows clearly on the keyboard. A glance checks it up with your copy. The machine itself newer errs. A child can do this, and a little practice develops wonderful speed.

Please prove all this You need this machine if you ever work with

It is made by one of America's largest metal workers

It has been adopted in thousands of offices, large and small It out-sells any other adder. Do not wait longer to try it

### Ten Days' Trial

We will send a machine on ten days' trial without any obligation Our local dealer will deliver it, or we'll send it express prepaid. Test it ten days, then discard it or keep it. Let the test decide

### The Industrial Need of Technically Trained Money Will.

The Possibilities That Await the Hydraulic Engineer.

By Chester W. Larner

CHESTER W. LARNER is hydraulic employer for the Wellman-Seaver-Morps Company of Eleveland. He has been shrifted with the hydraulic strokes deal try since 1992. He has designed hydraulic equipment for scater power developmen iry ance sove the has designed againstic equipment for scater power development in various parts of the United Histor, Unicion, and Canada, notable among which are the Electric Development Company of Niagara Palla, the Massisippi River Power Company at Kookuk, Iowa; the Urdar Rapida Manufacturing and Power Company of Montreal, the Onitario Power Company, and Shavishigan Water and Power Company, and Shavishigan Water and Power Company pany, Shawinigan Falls, Quebec.

He is a member of the American Society of Civil Engineers, the Canac of Civil Engineers, the American Novicty of Mechanical Engineers, associate member of the American Institute of Electrical Engineers. He is a member of the Cleveland Engineers and College Engineering Society.—Enrota.

for engineering, many lines of work are presented. Construction work is roughly divided into civii, mechanical, and elec-trical engineering, but these divisions an extent that it is neces sary for a specialist in one branch to have a considerable knowledge of the other branches if he is to be a well-rounded It is for this reason that most oral nature putit the last year, when the work becomes specialized Indeed, it is an open question if all undergraduate engineering courses should not be alike, leaving specialized work until the post-

Hydraulic eugineering in its various applications offers many opportunities to the young engineer. The great works of this unture in progress on every hand are constantly attracting public attenti Canama Canal, the great irrigation projects of the West, the numerous water power developments all over the world. water supply systems for large cities, and the improvement of navigable rivers for water transportation, all suggest great present and future opportunities for the hydraulic engineer

People at large do not as yet fully approclite the growing importance of water-power development to the industrial and civic progress of this country. Although the development of water-power in small quantities for various industrial purpose has been common for many years, it was not until the perfection of the alternating current generator made long distance transmission possible, that it began to re ceive any marked attention. The hydranlic turbine or water-wheel has been, from its inception, the most efficient prime mover known, but until long distance electric transmission became a commercia: perceibility, water-power development was rethat time, the power developed had to be used at the place where it was generated. But water-power sites are usually remote from large cities or industrial centers, where a good market for bower exists This gap is now bridged by the long dis-tance transmission line. The fact that a good power site is many miles from a go power market no longer prohibits the de velopment of that power. Plants are now in successful commercial operation, where the power has to be transmitted more than two hundred miles, and doubtle with the further development of electrical apparatus this distance will be materially

try is now in a state of marked activity. uid the development is certain to keep step with the increase in the demand for electricity. Furthermore, the demand for electric power is certain to be far out of proportion to the present normal increase, due to the growth of our population and our industries. Water-power is ordinarily cheaper than steam power, and lower cost to the consumer stimulates the use of electricity not only for purposes for which i railroads, electro-fiended processes, and other power as the electrofiend of wise medium for catching metallurgical work and many other for complete for complete

To the young man with a natural tastever to haul their trains, and no doubt the next twenty years will witness extraordimary progress in this direction. The atuminum industry in the United States and Canada slone is now using several hundred thousand horse-power of electricity. are at present far behind those of Europe, and the next decade will anguestionably be marked by unprecedented growth along these lines.

The young engineer in search of a profit able field for his efforts will do well to consider the opportunities afforded by water-power engineering. Many import nut plants have been aiready built, but no yet the field has hardly been scratched The latest estimate of water-power developed in this country is about 5,000,00 horse-power, whereas the undeveloped horse-power is roughly estimated at be tween 60,000,000 and 80,000,000. Further, more, practically all of the important been extending and increasing their capac-ity ever since they were built. Then again, many of the older plants are rebuilding and modernizing their conjument. This is a continuous process which will never end, and suffices to show that the work of the water-power engineer will not be fin ished even when all of the water-po is developed.

Handling water under low heads and at correspondingly low velocities is a difoblem from handling it under high heads, where the velocity may be as high as four or five hundred feet a sec ond. The tremendous force of such a stream can be appreciated only by those who have witnessed its d structive po It will penetrate solid bodies as fectively as a drill, and in turn is itself nimost impenetrable. It is impossible to shoot a rifle bullet through a high-pres jet of any considerable size, and the blow of an ax will rebound from it as if it wer a bar of steel.

The character of the plant in all its features must naturally change to suit these different conditions. The water must be diverted from the source of supply in different ways and different methods must to convey it to the pow house. The design of the power hou the machinery must vary to suit co tions, and sometimes steps must be taken to regulate the flow of the river by means of controlling works built many miles from the plant. Often the water will be taken directly from the pond or forebay into the wheel chambers, and again it may acted for miles through tunnels or pipe lines to the plant, necessitating elaborate precautions to prevent bursting of the conduit if the flow of the water should be suddenly ch

Such are the conditions which the hy draulic engineer has to face to-day. There is no lack of opportunity and there is no dearth of work. Men of ability and exmce are unquestionably in demand and no man taking up this work at the present time will fail for lack of oppor

A STATE OF THE STA

The 1914 Hupmobile is in the hands of Hupmobile distributers.

We believe this new Hupmobile to be the best car of its class in the world.

By best, we mean best in internal essentials, especially. We mean best in those things which make for long life and continuous service at lowest cost.

But we believe you will also pronounce it the most beautiful car of its class in the world.

We believe we have put more money into the chassis than any car of its class in the world.

We base these beliefs on our conviction—

That the production of this new Hupmobile than any car of its. sh grade steel That this new Hupmobile is the largest user of alumnum—without regard to class or price—in the world;

That the frame used in the new Hummobile is the costlest piece of pressed steel construction used by any car of its class in the world;

That the Hupmobile long-stroke motor will out-pull any engine of its class in the world;

That the Hupmobile pressed seel body—designed by us and built by the balliders of Pullman cars is the costlest body used by any car of its class in class. world:

That Hupmobile sorings utilize a greater tonnage of costly steel - more than 2,000 tons - that any other car of its class in the world;

That Hupmobile bearing—Timken and Hyatt—are the best in the world; one whole Hyatt building being devoted to Hupmobile bearings.

We repeat-for readiness; for ruggedness; for smartness of style: for incress of fine for daily work on the road; for extrement economy-we believe this new Hunner to be the best car of its class and

### Sir Oliver Lodge's Address

O much emphasis has been laid by the daily press on the few generalizations affecting psychi-cal research which Sir Oliver Lodge embodied in the conclusion of his presidential address before the Birmingham meeting of the British Association for the Advancement of Science, that the profoundly philthe Advancement of Science, that the protoundly pair-coophical and critical estimate of modern scientific achievements to which the major portion of the ad-dress is devoted is apt to be overlooked. To those of our readers who take an interest in this present transition period of physics, chemistry and biology we would commend a careful reading of Sir Oliver Lodge's text us it appears in the current number of the SCIENTIFIC AMERICAN SUPPLEMENT. Noteworthy as most of the presidential addresses delivered before the British Asociation have been, Sir Oliver's unquestionably stands forth as one of the most pregnant utterances that have come from the lips of a scientific man in a decade

Surveying as from a mountain top with the unclouded surveying as room a momentum top with the new science by waging a conflict with the old, Sir Oliver characterizes the scientific period in which we live as one of fundamental skepticism—not the theological skepticism of old, but a deep-rooted skepticism which has all but rmined the long established foundations of scie Scientific men are beginning to ask whether the conservation of energy is always and everywhere vali whether the second law of thermodynamics is n somewhere disobeyed, whether the long known and well-established laws of mechanics hold true everywhere and always, and whether the Newtonian scheme must not give place to something more than a mere approximation to real conditions. Indeed, it is argued approximation to real coloitions. Indeed, it is argued by the new school that we have no faculty for ascertaining real truth. What we once regarded as statements of fundamental, unassatiable truth are now regarded as conventions useful only as quasi-explana-

Against this enshrining of vagueness as an idol to be worshiped, Sir Oliver protests. Much of it was brought about by the tendency to resolve everything into atoms. In that tendency Sir Oliver sees daugerthe danger that scientists may lose all sense of the con-tinuity of unture. His whole address is therefore a plea for continuity

in proclaiming itimself "an upholder of sitimate continuity and a fervent believer in the ether of space Sir Oliver Lodge makes a strong attack not upon recent scientific discoveries, but ruther upon those comprehenive negative generalizations from a limited poview, which are based on such experiments as those of Michelson and Morley on the velocity of light.

He is thus led to decry the principle of relativity.

If the principle of relativity in an extreme sense cablishes itself, it seems as if even time would become discontinuous and be supplied in atoms, as money is doled out in pence or centimes instead of continuously; In which case our customery existence will turn out

organs of sense and no ready response to laboratory organs of some and no ready response to laboratory experiments. While all the law of chemistry and physics may be applied without head to state of the result of contact. Six Oliver some to question the orar sufficient. There can be no doubt that a living thing, while it chey the laws of physics, also initiates processes and produces results that, without it, could not have occurred. "The behavior of a ship firing shot and shell," as Six Oliver picturesquesty puts firing shot and shell," as Sir Gilver picturesquely puts it, "is explicable in terms of energy, but the discrimina-tion which it exercises between friend and foe is not so explicable." No mathematician could calculate the orbit of a common housely, "A physicist into whose galvanometer a spider had crept would be liable to get becomens of a kind quite inexpitable, until the dis-crived the supernatural, I. a., literally superphysical cause." Accordingly Sir Oliver risks the assertion that "life introduces something incalculable and purposeful "life introduces something incatculable and purposeful amid the laws of physics; it thus distinctly appliements those laws though it leaves them otherwise precisely as they were, and obeys them all." He can see no logic in trying to explain psychical phenomena in terms of physics and chemistry. There is a deeper terms of physics and chemistry. There is a desper-menting involved in natural objects than can be ex-plained by the laws of physics and chemistry. There is a real result of the control of the control of the control animals to eat it in order to carry seeds. But these explanations cannot be final. We have still to explain insects. So much cannot be nacessary merely to at-tract their attention. We have return to explain this tract their attention. We have return to recapilat this competitive striving toward life. Why do things strug-gle to exist? Surely the effort must have some signifigie to exist! Surely the effort must have some again-cance, the development some aim." Scientific men are too prone to confine themselves to the mere machinery of existence. Because that machinery obeys all the laws of chemistry and physics, Sir Oliver finds that scientific men are blind to its other functions. "Science may not be able to reveal human destiny, but it certanly should not obscure it.

### Taming the Chagres River

HEN the United States Government entered upon the construction of the Third upon the construction of the Pazama Canal, it was realized that the most difficult physical problem confronting our engineers was the turbu-lent ('hagres River. A shallow and gently flowing lent Charges River. A shallow and gently flowing stream in the dry season, the Charges, fed by the heavy rains of the west season, is liable to become transformed within a few bours into a mighty torrettial river, with a flow comparable to that which piesses over Ningara. Falls. The calar runs approximately north and south: the Charges, flowing from the seast, intersects can cannal, approximately a fiv mid-length, and, at the

canal, approximately at its mid-length, and, at repoint of intersection, turns somewhat abrupily to the north and flows in a course generally parallel with the canal, to discharge into the Athantic Ocean. Manifestly, any plans for the building of the canal had to make ample provision for controlling these stupendous shoot waters and guiding them nafely to the sen. Under the plans for a sea level canal under the sea. Unuer use pans for a sea sevel chast under the French régime, and later as proposed by the minority report of the International Board of Engineers, it was proposed to construct, parallel to the canal, a large artificial channel, capable of carrying the Chagres floods clear of and without interference with the work of excavation—a stupendous and hazardous probitself. Under the plans for the lock canal as now practically completed, the bold project was conceived and successfully carried through of building an enormous successfully carried through of building an enormous dam across the Chapter Valley mear its Attantic end, and providing at its center a spillway opening, through which the food waters could pass unobstructed to the Attantic. Taking advantage of the dry seasons when the flow of the Chapters is insignificant, this spillway opening has been gradually closed by a dass of solid concrete, provided with suitable openings controlled by gates through or over which the flowd waters have passed in the rainy season. At the present write, the suitable varies are closed, and the core resultive. spillway gates are closed, and the once greatly dreaded Charges, transformed from 700 to friend, is performing its quota of the work of canal building by the formation of a vast inland lake, nearly 170 square miles in extent, which will afford some 20 miles of

miles in extent, which will afford some 20 miles of deep water navigation across the lathnus. Those of our readers who have had the good fortune to visit the Pannam Ganal during its construction will doubtlebs remember that when they reached the north-ren end of the Culeira cut, the train passed over a steel bridge about a quarter of a mile or more in length, which served to carry the tracks across a rather broad and shallow stream. This stream is the Chagres River, and the point of crossing is located where the Chapter an area case our customary existence will turn out to be no more really continuous than the events of a kinemantagraph screen, while that great agent of constitutity, the ether of space, will be relegated to the numerum of historical curtodities." That would indeed mean "the most fundamental revolution since Newton." Sir Oliver protests against the present denial of the existence of anything which makes no appeal to this, it follows that unless, some provision had been

made for preventing the feet made for payenting.

Culciving cut, the lattice would have bent a
the flood season with from 10 to 10
log the time of seasoning time. To see
artificial subsalanting, there as the Cambre
built from the railread continuous oute from the railress essential action the ound to the opposite side of the opin diche has served to keep also cut they desired of the exercised. The destricts of the exercised to the exercised through the bottom of the dike, through the bottom of the dike, through water has been drawn has

through the bottom or the size, Through where he water has been drawn by a pumpling ignest one structed specially for that work.

On September 18th all steam shovel, work were was gaspended in the Oulebre cut, and the conscruction such steam shovels, drills and over thirty-six undee of tracks steam shorels, drills and over thirty-six salles of treats, in now boing removed from the cut, prespectatory rie flooding it with water. The last work of the drill should be such as the present of blasting the six or severe handless thousand cutule yards remaining to be lating out of the bottom of the cut. This materials will the bestoom of the cut. This materials will be reseasoned by floating drudges, when the cut has been fijled with water. But if dones steam shorels, will be materials at root on the seek bank and four on the week bank; contribution of the cut has been fijled with at root on the temperature in the contribution of the seek bank and four on the week bank; and four on the cut has been fijled with the contribution of the seek bank and four on the cut has been fined with the figure of the banks to all the seek.

and diminish the joudency of the basile to silfe first-the caind.

The plan of operation for filling the cet is as fol-lows: First, on Cookee 6th, the four 28-tech five pipes through the 6the will be opened, and the water from Gatun Lake, which on Angust 28rd stood at 881. The feet above see level, will be permitted to feet stoo the cut for five days or notil Cetcher 10th; on which day

aut for 4ve days or nattl October 10th; on wylich day the Gambon dike will be drawminted and the intelle-er of the catending from the dike to the upper lock gather of the catending from the dike to the upper lock gather. The final act in this great engineering drawm will be played by the two coronom fourting dreades, the largest ever built, which have been constructed for the purpose of westling with the gigantic sidies of the delvie of the Gambon dike, and then, proceeding through the cut, they will france the processing through the cut, they will remove the broken rock, at the flast blacking above referred to. Having done that, they will attack the huge siddes which have been giv-ing so much trouble, particularly during the past four or five years. These diveleges have a combined espective of 1,200,000 cutch yards per mouth, and they are there-00,000 cubic yards per month, and they are fore well quelified for their task of removing the 9.000. cubic yards of sildes that are new moving into the m of the canal.

And thus the world's greatest work of engineeris will have been completed one year ahead of the the estimated by the engineers.

### "Smoke-proof" Buildings

FIREMAN of long and varied experience in the service of the New York city Fire Departthe service of the New York city Fire Depart-ment recently stated that of the hodies recov-ared from burned buildings, a surprisingly large num-per showed no visible effect even of being slightly secretably the finness, which means, of course, that a large proportion of the fatalities are due to simple asphyxiation. In the Park Avenue Hotel thre of some ten years ago, most of the guests who lost their lives were found, if we remember rightly, without a visible mark of fire upon their persons or clothing.
"So far as the fatal effects are concerned, the poison

ons games that accompany amoke are as deadly to human life as flame. Hence, if the lives of the immates of a tail office building are of greater value than the structure likelf, we should take greater pains to protect human life against asphyxiation than we do to protect the steel and masonry building against fire. But to re both of these results, it is necessary, not more ensured the building itself of incombustible mat to construct the building fuels of incombustible material, but to see to it that everything of a combustible nature in the way of strings and turnishings be most rigidity excluded. If the tons of wooden furniture in the lower stories over three or Rour hundred foot high building were abless, such the products of combustion, the mache and gases, were sweeping upward through stairways and elevator shafts and filling the varieties occritions, what earthly chance would the immates of the upper startes have of getting out of the building before they were overcome by sufficient for the process which has presuitly been made by 2 far. A 5.

All of which considerations give given force to the protest which has peeutily been made by Rr. A. G. Patton, manager of the Special Manards Department of the Sev York Free Immunes Explosure, aspine the plan of the Severi of Bettimate to equip our new municipal building with weeken office Teachtries We have buildings from their bundered to even knieffered Res and more in beights in the eith yorkey. simplifies year of aver one and one quarter million dollars. Highways hatigin Sairf-driven Street Care.—After a marked study of the motor buses and care of Parts and Enables, the Edithburgh City Council has been advised by its own Commission to adopt sairf-propelled street care in preference to a system either of overhead or of cinduit steets ear service. The Commission reports in ferred of parolibe-electric care, on the ground that the high kilph once of these is smooth than counterbalanced by this givest cost of installing an overhead or underground scales written.

this great cost of instanting an overcose or uncorpromeneally system.

"Ethe Ballways is the United Stetes.—Assorting to the singlishes of the Interstate Commerce Commission for the fiscal year ending June 30th, 1912, there are 240,— 283 miles of track operated in the United States. The examps number of isoconcives per 1,600 miles of line was 286, and the average number of cars was 9,860. The total sumber of persons on the payrolis was 1,969,— 218, and the total wages and salaries paid amounted to 1,248,113,172. The par value of the amount of railway capital outstanding was over nineteen and one half hillio 1 delice.

collain.

Statistics of Railway Accidents.—The report of the Interestate Commerce Commission shows that during the months of Oxtober, November, Desember, 1912, 269 people were killed and 4.334 were injured in urin socidents. Casualties of all classes amounted to 2,67 killed and 61,232 injured. The total ampine of collisions and desallments for this quarter compared with those for corresponding quarters of the four previous years shows that with the exception of 1911, the number has increased of 46.8 per cent over the corresponding quarter of 1908.

A Herreabest Yacht for the Defense of "America's" Cap.—We shall not be surprised if the reduction in the size and cost of up defenders for the paces of next year results in the construction of several yachts to contend for the honors of being selected for the defense of the cup. We are pleased to note that Herreahoff, who has contributed so greatly to the retending of the cup it is sometime to present years, has been commissioned to huitd a 75-foot defender for a syndicate composed of former Commodere Commisse Vanderbills of the New York Yacht Club, J. P. Morgan and Frederick G. Bourca. As usual, Herreshoff has been given a free hand in the matter of the design of the yacht and its cost.

That Revelving Ship Again.—The revolving ship is one of those inventions which, although they are obviously impractioable, seem to have a fascination for the inventor which is rather difficult to explain. Several years ago these was built and tried in this country a boat of the revolving type which, if we remamber rightly, reached a stage as which it was launched and an atempt was made unsuccessfully to propel it. According to a dispatch from London, a Pats inventor is now busy upon another of these craft, and judging from the meager descriptions available, the designer is following along the lines that were proved to be altogether impractisable fully a drone years are:

fully a dozen years ago.

A New York Central Safety-Enhibit Car.—A safety-sahibit car, for use in connection with the work of the safety department of the New York Central Lines, lase recently been put in service. It will serve as an instruction car, in isseabling the principles of 'eafety firet' to the employees of the railroad. Along each side of the car are models of the machines used in the different shope to safequed the workman against injury. By means of photographs arranged on the walls, the "safe" and the "unsel" methods of doing various kinds of work are depicted. Other framed pictures show how the contest show that, annuality, over 10,000 Seepassers are killed and injured on the railroads in the United Shates.

States.

German Dreedweaghts to Curry 15-Jack Gens.—It seems to be prestry excisin that the bissay German drend-noughts will be nared with 15-took guns. If so, the German hatcheshape will send the world in the power of the individual units of their main hatestries. The cartisat German hatthiships, exceptionfling is due to our "Oragon," were arreed with a gun of only about 9½ incises salide. The next astrone was to as 11-took place; then in: 8 15-took, which is the gun with which the ships of this extend place; then in: 8 15-took, which is the gun with which the ships of the extend places made and the present astrone or as Te-fraids place with he much larger thing the more entragements of earlier would insideable to the large mind; for which the salidity of the salidity of earlier would insideable to the large mind; and the proposed, the shall for the different gun, will be probably about 1800 persons in weights.

#### icience

The Primes of Monnec, well known for his researches as an oceanographer and as a patron of science, has announced his intention of paying a visit to some of the principal scientific institutions of the United States in Southenheer.

A Deep Bering in Berissisis is furnishing interesting information concerning the geology of that island group. The boring was undertaken by the management of the Princese Hotel, Hamilton, in the vain hope offending water for volcanic origin," as the present local supply is mainly rain water, caught from the roots of houses and strong in citizens, and is unadequate. A depth of over 1,400 feet has been reached. Samples of rook, etc., have been taken at various depths, and one set of these has been presented to the United States National Museum in Washington. Petrographic studies of the material are being made by Mesure. L. V. Pirson and T. W. Vaughan, while Mr. J. A. Cubman is studying the foraminifers for a report on the peleontology.

Matesif's Comet.—A telegram received at Harvard College observatory from Prof. A. O. . Leuschner, of Berkeley, Cal., gives the following elements and ophemeris of Metoalf's comet, computed by Prof. Crawford and Miss Levy, from observations on September 2nd, 3rd,

The comet's perihelion passage occurred on September

The Harmstine is a dry north to east wind that blows in winter on the upper Guines coast in Afrea. While it prevails the air is filled with fine dust. The characteristics of this wind are most easily explained on the supportion that it comes from the Sharaz Desert, and is analogous to the "ghill" of Tripoil. However, the extensive burning of grass which goes on at the harmstian season might account for the remarkable outlines of the wind. In order to help obsides the origin of this wind, Capt. von Seedred, stationed in Togo, has recently collected specimens of harmstian dust with the sid of aspirators and filter-tubes. These were examined in Berlin and found to consist mainly of sillicotus fragments of diatoms, indicating a deservicing. Vegetable sals was present, but evidently the burning grass merely intendifies the initial dustiness of the harmstian.

of the harmatian.

Natural Riseory Manuals for the Philippines.—

Travelers with a taste for natural history who vasit the Philippines will do well to equip themselves with some of the excellent manuals published by the Bureau of Sciences a Manila. These included "A Flora of Manila" which is practically a complete flora of the actiled areas at low altitudes throughout the arbipleago, containing descriptions of over 1,000 species, with artificial keys, selected native, Spanish and English names, and accounts of habitats, time of flowering, and range of all spocies considered; "A Manual of Philippine Birds," containing descriptions of all known species of Philippine birds, with the usual keys for the benefit of the novice, maêtre and English names, information as to range, and in many cases notes on nesting, migrations, and other habits; also "A List of the Mammals of the Philippine Binds, exclusive of the Celacos," and "A Chéck-list of Philippine Fahee."

Cheick-list of Philippine Fishes."

Human Geography and Industry-planning.—In a paper presented before the Birmingham meeting of the British Association for the Advancement of Science, Mr. C. R. Enock maintained that the economic problems before the world at the present time call for the stabilishment and exercise of a comprehensive and constructive science, whose aim would be to evolve and teach the principles under which economic equilibrium in the life of communities may be attained. It was argued that the real science of living on the carth, or "human geography," the adaptation of natural resources and national potentialities to the life of the community, has zeror been formulated. The congestion of the population in towns, the desection of the countryside, the high cost of living, low wages, unemployment, and so forth, are related phenomena, luminately connected with the echieveston and development of natural resources. The axion was advanced that the world is espable of supporting all lies labalitants in sufficiency, and its failure to do so in due to the non-energence so far of an organizing science, whose deliberations would be safer freeze agoistic der partiess influences. It was afficued that the teaching agis poperations of such a science is inconsury if feeded resource and to the humanitations and privite of the same polation to the algebre of things at their corresponding institution do to physical, security in antiention to the physical, security in antiention to the physical, security in antiention to the physical security and extension and other sciences.

#### Automobile

Two Automobile Shock Absorbers.—Two patents, Nos. 1,066,919 and 1,006,920, to Theo. A. Klenke of New York city and Frank N. Bochrich of Jersey City, N. J., sasignors to Klenke Cushion Axie Company of New York city, previde pneumatic cushions supported upon the axies and operating to cushion the vehicle.

Automobile Starter and Lighter.—In patent No. 1005-999, Morris Monkowitz, of Montelair, N. 3, shows a motor vehicle in which the speed of the motor generator can be substantially the same as that of the crank shaft when the motor generator is driven by the engine as a generator to charge the batteries. The power of the motor generator can be gradually applied to the crank shaft during the starting of the engine.

One Hundred Horse-power Gan Wagons for Austrias Army.—New 12-ineh siege mortars of the tubular-rosoil pettern, with the tube 14 feet in lenight and equal to projection, and the tubular should be suffered by the pettern of the tubular should be suffered by the pettern of the suffered by the suffered by

Another Spring Wheel.—On account of the unavoidable, inherent dusadvantages of the ordinary type of pneumate anatomobile tree, designers have been striving for several years to bring forth a tire with puncture-proof qualities, yet retaining the necessary resiliency to afford desirable rating qualities. To this end one wheel manufacturer in particular claims to have solved the problem and will place his product on the market his month. The fundamental idea of the wheel as the carrying of the load on horizontal helical springs connected alternately to the outer and niner runs with ball and socket connections. There are 11 of these springs arranged around the purplayer of the wheel rim in such a manner that each spring carriers 1/14 of the total load on the wheel. When the car strikes an obstruction the shock is communicated through the sholl rubber the and is taken up by the reaction of the belief apprings. The center of the wheel is undo in the same way as any ordinary automobile wheel but it is lateral strength is increased, since the spokes are much shorter than in the small construction.

Meaning of Standardization to the Individual Motorials.

"Unfortunately, the doings of the Society of Automobile Engineers are not advertised as widely as they might be advertised and as a result there are few who appression of the true meaning of the society's activities to the individual owner. One of its landardization of magnetic mountings, or amount of the society's activities to the careful of the society's activities to the society and the society activities to the standardization of magnetic mountings. The mere statement may mean next to nothing to the animatised but a little desper delving brings to light list advantages. If the mere statement may mean next to nothing to the animatised but a little desper delving brings to light list astatistic for it means, briefly, that if John Smith is not satisfied with the magneto on his machine be may substitute for it includes the more of the magnetic delivers that the form of the state of the more of the magnetic delivers the server of the server of an expective of the mean temperature of the server threads at limits any or will the portance of this step to the individual owner list in the fact that he may not purchase at almost any hardware replace one loss the product of the server thread at the consumption of the most important and the importance of this step to the individual owner list in the story or country general story a standard thread and to go for a nut or both c—and then to pay for it in proportion.

The British Treek Show.—While this country has ber motor truck shows every your and in almost every eity of importance, England follows the bolley of exhibiting only every half decade. In the British Commercial Motor Volide Show, which recently closed, at Olympia, the first in five years, the keynote was at Olympia, the first in five years, the keynote was at Olympia, the first in five years, the keynote was considered to the following the process of the second of the foreign the foreign that is done at our own annual truck displeys. England has awakened to the fact that the displeys England has awakened to the fact that the displeys England has awakened to the fact that the displeys of the following the fo

### The Steel Car as a Life Saver

### Telescoping is Prevented by All-Steel Construction

In the recent wreck on the New Haven Bailroad, the heavy colliding engine and train split entirely apart het vor rear wooden steeping cars of the train abead, scattering the wreckage and the helpless passengers to tight and left as it crushed its way through. Over a score of teophe were killed outright.

It is beguing the question to say that had the earbeen of silated construction, none of these lives would inverbeen test; but there is abundance of evidence, drawn from the behavior of steel cars under conditions practically as severe as these, to show that steel construction would have saved the lives of many, if note of the greater part, of the occupants of these two rear curs.

In the event of a newy collision, wooden cars fail, either by golur entirely to phere as in this case, or by one of the massive and strong underframes mounting upon another, and shearing the superstructure of the lower car entirely from its lane. Wooden construction has the disadvantage that, although its strength to resist the first shock is great, one it has given way it offers but little progressive resistance to the crushing and rending energy of the collision; whereas the tough mental of which steel cars are built, not only offers a men's greater resistance to the first shock, but, after the car or cars have begun to give way, the material still puts up a simbour girls to retain its original form.

The behavior of trains of steel cars in collisions shows that the end platforms and weekblues, which are not or should not be occupied by the passengers when the train is in motion, form a natural buffer and "yield-point," and that the first concept of the collision, and generally the whole of it, is expended in crumpting up the veetfluies—furthermore, this usually occurs without uny loss of life

Although the steel our will save its lumates from the crushing hipries which result in more or less speedy death, it cannot sufferment them from the contustons due to the sudden arresting of the train and the hurting of the passengers forward or backward, according as they are in the train which strikes or the one that is run into

These facts are brought out in a report of the Internative Commerce Commission on the wreek at Tyrone. Pa., ou July 30th, on the Pennsylvania Rallroad, in which, although 153 people were more or iess injured, only one was killed. This collision was an almost exact duplication of that at North Haven on the New Haven Hallroad. A truit sainding on the track was struck in the rear by a fast train. Not one car in either train was of wooded construction, and the only domage

resulting was the crushing in of the vestinites. The heaviest damage, of course, was done to the rear car, which was crushed for ten or twelve feet in he rear, while the forward end was jammed for six or eight feet into the rear of the ear sheed. Subsequently to the New Haven wreek, a fast train was ditched near Wyllo's station on the lemaylyania Raliroad on September 9th, and although six steel concless were fluing from the track and turned over in a cornfield, only 35 persons were fluing from the stack and turned over in a cornfield, only 35 persons were fluing from the stack

By way of showing the great resistance the accompanying itlustrations of a wreck which occurred in July of this year on the tracks of the Northern Pacific Railway in the State of Washington, in which three passengers and one emptoyee were killed, and seven passengers were injured. The train consisted of a 200-ion engine, followed by three refrigerator curs, one combination buggage and express car, three day conches, one dlubug car, oue Pullman sleeping car and one observation car, making ten curs in all. The train which was making up lost time jumped the track when it was running at a speed of sixty miles an bon. The engine rolled over into a gravet embankment, and the whole train was brought so suddenly to a stop, that the shock was not much severe probably, than that of a direct The forward truck of the first steel day couch was knocked from be-peath the our, allowing the forward end to drop and causing the rear end of the car ahead to mount the underframe and crush in the left-hand side of the car to

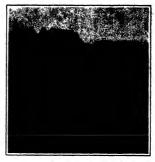

the extent shown in our illustration.

When we remember that this 15 or 20

feet of the car had to absorb the enermous energy of the six rear cars, running at 50 to 60 miles an hour, the great resistance of the steel construction will be evident.

### The Meteorological Service of Australia

BEFORE their federation, each of the Australian Bstates had its own meteorological service, in most cases in connection with an official astronomical observatory. Some of these institutions made

Looking forward from the roof of the dining car.

weather forecasts and even published weather maps, but the work suffered from lack of co-ordination between the states, and was but meagerly supported by the several governments. The main outcome of these rather desultory efforts was the collection of a considerable bod of cilmatte statistics.

In 1897 a general service was established for the whole commonwealth, with headquarters at Melbourne, and piaced under the direction of Mr. H. A. Hunt, who still holds the post of "Commonwealth Meteorologist." Mr. Hunt's first important official set after his appointment was to make the circuit of the globe, visiting kindred institutions in other countries and picking up idean. Since his return to Australia practical meteorology has made great progress in that part of the

THE LEVEL CONTROL OF THE PARTY OF THE PARTY

Observations made every moreling at 9 o'teicis at four bandwel and forty-two stations are transmissed to Melhourne by telegraph. Besides reports from places in the commonwealth, valuables advises are presirved. From the constitution of the constitution of the Atlanctic and Mew Years between Australia and the Atlanctic and Mew Zealand to the south, and Ristavia to the north. Thus the cotal area embraced in the weether charts, which are published both in separate broadles from and in facility energapers, as in the United States, which are published both in separate broadles from and in facility energapers, as in the United States, is considered infector to that above, no United States, is considered in the Control of t

In its method of pregaring forecasts the Assessitian service is unique. Several forecasters work together at the central office. Most of these have had expertence as local forecasters in one or asother of the states, and each is regarded as an expert for his own district. However, each of them writtes out forecasts for all the states, and these are submitted to the commonwealth meteorologist, who prespares an independent series of forecasts of his own. A conference is then held between Mr. Hunt and his staff, and the forecasts that ullimately go out represent the consensus of their opiaions. During the year 1912 about 87 per cent of these predictions were verified.

As to particular phases of the work, there is a special service of warnings for the northwest coast of Australia during the willy-willy season, between November and April, and another for the drying season in connection with the fruit settleneous at Renmark and Mildura, on the River Murray, analogous to that which the United States Weather Bureau maintains in California, A flood-warning service is also maintained, especially in Queensiand, where the rivers are short and torrestial.

### What is Coca?

THERE is no more remarkable plant, if regarded from an economic point of view, than Brithwood coor, although as a plant it is not well known in the hotanical world. From its leaves is obtained a nar-coit which is considered a simulant and tonic and is used extensively in Pern, Reuador, Chiti, Bolivia, and other parts of South America. It is used both as a remedy for various diseases, and also as

remoty for various diseases, and also as a nervous stimulant and restorative. It is said that by chewing a sufficient quantity of coca leaves, a man is capable of dispensing with food for five days without any material inconvenience, even though he is engaged in hard physical labor.

Con leaves, which are small in their fresh state, and light green, are produced by a small shrub shout 4 feet high. The flower is white and the fruit a small red berry. The plant is propagated by seed in beds and later transplanted in the open at the beginning of the rainy season. Cook is grown on a commercial scale, chiefly in Peru, where a crop of leaves can be obtained every four months, eighteen months after planting, and for many years, if the plants are not destroyed by the ants, which are so destructive in the tropics. As soon as the leaves are gathered they are, thoroughly dried to avoid any moisture or dampuses after storing any moisture or dampuses after storing

Brythrogston cocc is a plant which grove in moist and woody regions chiefly on eastern slopes of the Andea. Much attention has been becomed upon its culture, which has increased the supply to such a degree that during recent years many hundreds of thousands of dollars many hundreds of thousands of dollars. Unlied Rates uses large quantities of these leaves annually. The average value of this product used in this country amounts to about \$155,000. At the present time Pers turnshass the olls of the occa leaves used outside of that country. The plant has been introduced, into indials, Orgion, Javas, and other parts of the Best.

Derailment of a ten-car passenger train running at a mile a minute.

This steel car bore the brust of a wresk at 60 miles per hour.

THERE can be no doubt but the increasing adoption of electric traction, though ousting the steam locomotive from its unrivaled monopoly, is indirectly renaible for a number of improvements lately adopted its design. However, a common competitor is now arising in railway traction to both types of prime mov-er, vis., the Diesel or high-compression oil engine, which after its recent achievement in ship propulsion, It is significant of the high development reached by the oil engine that the first Diesel-motor operated locomo-tive should be, not some modest engine designed to haul the student of the same motives engine designed to have a suburban or slow train, but an express locomotive destined for service on the Berlin-Magdeburg trusk line. This Diesel locomotive, the construction and trials of which have been watched with unusual intertriats of which have been watched with unusual inter-est in German engineering circles as well as abroad, was supplied to the Prussian Hossian State Railways by the Geedligheaft für Thermo-Lokomoriten, founded by Mesens. Gebrüder Sulser of Winterthur, Switzserland, Govariment Engiteer A. Klose of Berlin (who is re-possable for the design of the sechanical part of the locomoritee) and Dr. Rud. Diesel of Munich. It has been constructed at the wortshops of Mesens. Gebr. Sulser, who designed the engines.

The motive part of the icomotive mainly consists of

The motive part of the locomotive mainly consists of a driving engine direct-coupled to the driving axles and an auxiliary engine working quite independently of the driving axies. This has an output about 1/5 to 1/4 that of the main engine and serves to generate comthat of the main engine and serves to generate com-pressed air, for operating the main engine in starting, on heavy gradients, etc., with high charges. Moreover, in order to increase temporarily the output of the auxil-lary engine, there have been inserted between it and the driving engine, air tends from which a certain amount of air can be derived during standstills of the auxiliary motor or even while this is working. In Fig. 3 is shown Messra Suiser's patented arrange-

In Fig. 3 is shown Meeers. Suitser's patented arrangement of the driving said auxiliary engines. a is the driving engine coupled to the driving axies b, the engine to meet the special requirements of locomotive operation, being reversible; o is the auxiliary engine which serves to drive the compressor a supplying compressed air through the conduit so the driving engine o, there to be used as starting or fuel injection air.

In starting, the auxiliary engine o is kept working, thus throwing a continuous supply of compressed air into the main engine. The latter can thus be given a considerable inflow, which may be even increased by gupplementary air from the tanks p. Compressed-or purplementary air from the tanks p. Compressed-or operation sions allows the train to be accelerated up

to 8 to 10 kilometers per hour, after which fuel operaproceeded with, the engine now working on the constant pressure (Diesel cycle). There is

another means of air-supply available. stead of deriving the whole of the compressed air from e coupled to the auxiliary engine, part of the

Starting valve and gear.

gine and part by the driving engine, these being like ise made to operate pumps.

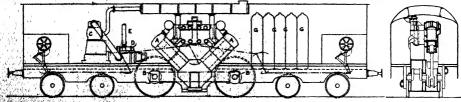

The above is the general arrangement of the Diesel locomotive. In the following are discussed the mode

The express train locomotive herewith represented The express train iccomotive nerwith represented is 16\textit{\textit{m}} interest in length between buffers, and 05 tons in weight in full working order. The coupled wheels are 1.75 meters in tread circle diameter. The driving energy is transmitted from a loose shaft to the coupled wheels by coupling rods designed in the to the couples wheels of the rods are fitted with adjustable journal brasses.

The main frame is of the box pattern. It carries in

its central part the support and driving bearings of the driving engine; this support consists of a steel casting and serves to carry the loose shaft. The motor cylinders are also held by cast steel cross-ties. At one end there is fitted the base of the auxiliary engine. The frame cross-ties, made up of sheets and angles, carry the bogie pivots and at the same time serve as coupling boxes to receive the draw-bars. The draw and buffer gears are designed in accordance with offclai regulation by the Prussian Rallway Department. The driver's cabin takes up the whole length of the locomotive, thus protecting the driving gear. Tauks are fitted into each of the four corners of the locomotive body, those at one end serving to store cooling water, and those at the other cud, cooling water and water, and more at the other run, coming engine, there is situated the exhaust tank; above one of the driver's stands a honeycomb radiator, and above the driver's the evaporation cooler Two pumps, driven by the stands a noneycomb radiator, and anote the orner, the evaporation cooler Two pumps, driven by the main and auxiliary engines, respectively, ensure the circulation of cooling water, the drawing off of piston cooling water and the raising of fuel from the tank.

The driving engine is a reversible four-cylinder sin-gle-acting Sulzer motor, designed on the two-cycle principie. The four working cylinders are set by pairs at an angle of 90 degrees to one another, and all of them at 45 degrees to the plane of the track (in V-fashion). stroke Each pair of working cylinders is situated in the same plane and made to act on a common crank pin, the rods being forked so as to insure perfectly symmetrical effects. The two cranks are set at 180 degrees and are designed to run at 304 revolutions per minute at a traveling speed of 100 kilometers per hour. The crank shaft carries in addition to the two working cranks at the outside two pressed on crank disks with balance masses, transmitting their rotation through coupling rods to the driving axles of the vehicle. By this patented arrangement a perfect bal-

ance is insured between the primary forces of the ance is Distrect netween the primary forces of the reciprocatting misses of the working cylinders and the contifunal forces of the caulty coupling rods and balance misses. Each cylinder carries a fuel valve, a starting valve and two scavenging valves for the injection air (at 50 to 70 atmospheres), starting sir (at 50 atmospheres) and scavenging air (1.4 atmosphere + absolute). The exhaust is discharged through silis in the cylinder wall, which are opened and closed again by the piston. Between the crank disks and the frame there are two eccentries, each controlling all of the valves of one haif of the engine and which can be turned round in reversing the motor, when the traveling direction is to be changed. This is done by means of a special rigging d, a, f (Figs. 1 and 2). The position drawn in full of the lever c corresponds to word running, the position drawn in dots and da to forto backward running of the motor. The motion of both eccentries a is transmitted by rods b to the two lever shafts c, which actuate in their turn valves in the cylinder covers. In the cylinder visibile to the right, there is marked the steer-ing of the fuel valve, whereas the steering of the seavenging valve is limitarised in the left cylinder (on the other side of the vehicle). The steering of the fuel valve is so designed as (a nilow various degrees of admission to be obtained, by altering the posi-tion of an intermediary piece y. The two fuel pumps, the pistons of which (four in all) are likewise driven from the valve gear, are not shown in the figure. starting valve is controlled in a similar manner to the thei valve. Variations in the duration of opening of the starting valve (which are obviously more considerable than the range of variation of the fuel vaive) are effected by turning round the shuft k on which the intermediary piece o connecting the valve gear and starting valve is mounted. In front of the starting-air valve t there is inserted into the starting conduit k another organ l, which is likewise controlled by r and

netnated from the coupling rod m.

The arrangement of two steered organs in the startinguit conduit allows a constant admission of air (preingsuir conduit miows a consumit indimission of air (gas-closis to the entrince of fue) to be adjusted for, while reducing losses due to throttling. With a single start-ing valve it would be difficult to so design the vulve gear as to keep this six admission constant with all gear as to seep this air admission constant with an degrees of adulasion intermediary, as in the present case between 0 and 68 per cent. Throttling valves, on account of their slow opening and closing, would like-wise result in material losses. These drawbacks are obviated by the arrangement above described

Between the four working cylinders of the driving engine there are placed two double-acting reciprocating pumps, and beside these, a three-stage injection air pump, all three pumps being operated from the two connecting rods of the two front working cylinders, by the intermediary of balance beams and articulated rods,

the intermediaty or manuscular manuscular road, and fitted with safety valves

The injection air pumps serve as stand-by for the
unxiliary engine our pumps. Should the auxiliary engine, for some reason or other, be unfit for working, the injection air pump would be able with normal speed and moderate loads on the driving engine, to supply a sufficient amount of injection air.

The maillary oughe is likewise a two-cycle Die motor, its output being 250 effective horse-power. comprises two vertical cylinders of 305 millimeters bore compasses can extend symmetrs of some minimeters our and its millimeters stroke, and its supplied with fuel by a two-ploton fuel jump. The connecting rods of the two multiple-stage horizontal sir pumps are arranged to act on the two motor cranks set at 180

The driver's cable contains four hand-operated wing pumps, three of which serve to fill the cold water, and circulation condults, even in case of standstill of the two engines, whereas the fourth one communicate with the forced lubrication of the driving engine, thus allowing any gearing parts inclosed in the erank casing to be intricated in case of standstill of the locomotive. The conduits are led to both ends of the locomotive, thus allowing all cooling water compartments and conduits to be readily discharged

each end of the locomotive there is a driver's stand comprising the mechanism for reversing the main engine and the following arrangements: Levers for throwing the starting and fuel valves in and out of gear, a lever for controlling the amount of fuel rab by the fuel pumps, the starting head, the braking valve and sunder, the signal whistle and various gages.
The following operations are required in getting the

locomotive reads for starting, in stopping and in re-

Starting .- The starting-air valve at the starting head being slowly opened, atr is allowed to flow from the starting tanks to the starting valves of the engine; the ressure rises slowly and the engine begins rotat-The charge supplied from the starting valves is ed, while the pressure rises. When a speed of about 10 kilometers per hour has been reach the starting-air valves are thrown out of gear, and the

fuel vaives are set working. The toemsotive then is hi normal working order, the charge of the fuel pump and the pressure of the injection air being controlled in nce with the speed and output.

Stopping.—Throwing the fuel valves out of genr and actuating the brake valve.

Reversing .- By turning the hand-wheel round in the driver's stand, the valve gear is adjusted to backward running. A blocking arrangement prevents the engine from being reversed, while the fuel valves are thrown, but gear. In sarring, stooping and traveling, the same operations are performed, when going forward

same operations are performed, when going inswaria and backwarf, respectively.

After some preliminary trial runs on the Winterthur-Homainston line, the locomotive was taken under its own power to Burlin, partly hauling on its way a fast notive at a speed of 70 freight with its steam locor eters per hour; the traveling speed, in accordance with time-tables, varied between 20 and 180 kilometers.

### Commissioner Moore's Last Report

In his report of Angust 14th, 1913, to Congress for the year ended December 31st, 1912, Mr. Moore, the retiring Commissioner, shows the receipts of the office from all sources to have been \$2,118,158.30, and the expenditures \$2,022,000.11, leaving a surplus of 100 experiments \$2,002,000.11, rearing a surprise \$196,092.19 and the amount of the total net surplus ling carulings of the Patent Office, deposited in Treasury of the United States, to be \$7,160,017.95.

In proportion to population more patents were issued to citizens of Connecticut than to those of any other State—one to every 1,150. Next in order are the following; District of Columbia, one to every 1,229; California, one to every 1,434; New Jersey, one to every 1,50%; Massachusetta, one to every 1,50%; Illinois, one to every 1,639; Colorado, one to every 1,711; New York, one to every 1,786, while South Carolina is last in the list of States with one patent issued during the year to every 18,040.

The report includes some statistical tables covering a on of the business of the Patent Off 1837 to 1912; the first patent and the number of patents d in each year; the number of patents is the United States and foreign countries from the earli est period to December 31st, 1912, and an intecomparison between the receipts, expenditures and volof business done in the years ended December 31st, 1899, and Docember 31st, 1912, which shows the per-centage of increase is greatest in every item except the number of employees, indicating an increase in recelpts and in mass of work without a proportionate increase, but rather with a proportionate decrease in increase, but rather with a proportion the number of employees of the Office.

### Loss of the Zeppelin "L-1"

W HILE flying over the North Sea toward the Island of Heligoland, during the maneuvers of the German high sea fleet, the airship Zeppelin "I-1" was struck on September 9th by a violent gale and hurled into the water, carrying with it the twenty-two officers men, of whom only seven were saved.

This is by far the most disastrous calamity that has overtaken any country in the development of its dirigibles, and no less than construction reigns in German aeronautic circles Among those who lost their lives were Capt. Motzing, commander of the marine alreship division; Capt. Hanne, commander of the wrecked Zeppelin "L-1," and Baron von Maitzahn. It was also orted that the naval commission appointed to super se the trinis was on board The storm which struck the lii-fated airship came up

o suddenly that there was no time to make a landing. As the officers and crew were bravely maneuvering to As the oncers and crew were bravely manedvering to bring the big envelope into the wind a heavy gust sud-denly struck her amidships and hurled her into the sea, where, after an hour, she succumbed to the postuding of the waves and sank with fifteen of her officers and When the storm first struck the ship a wire was sent out to water craft lying in the vicinity of Heligoland. Torpedo boats were immediately hurried to the spot, but succeeded in rescuing only seven of the

The Zeppeliu "L-1" was a naval dirigible, the pride of the German navy, and was completed only last year, making her first ascent from Friedrichshafen on October 7th, 1912, and leaving there on a long reliability trial a week later. On this trip Count Zeppe offity from a week mer. On this easy counts appears was in common The ship carried twenty other offi-cers and members of the crew besides nearly three tons of fuel. She flew to Johannisthal in thirty-two hours and successfully established wireless telegraph com-munications with a number of German stations on the

The slilp had a displacement of 22 tons and a capac-The silp man is enjacement or 22 tons and a cepacity of 770,000° cubic feet of gas with 18 seeparate gas chambers. She was \$65 feet long and \$6 feet in than-cter and was equipped with three Maybick motive totaling more than 500 horse-power, due of these motors being pieced in the forward car and two in the same. The motors drove aluminium propellers, those in free in

having two liades each, and these in the semi-ticates each. The large statedly was displaced a of 60 miles per lour. look, at a langer or 500 sect, mining tour Property moreover. Before the nocidisate to the "f-d" the latest Reppeths to meet destruction was the inhitary dirightle "L.E.-18," which was pounded to pieces by the wind after having weathered the storm for amieteen hours. A torief secount of this accident was given in the Senseristic American of April 5th last.

### Automatic Train Control

THE recent disaster on the New York, New Haven and Hartford Bailroad will doubtiess bring out the usual demands for the installation of automatic stop devices, rendering it impossible for the engineer of a train to run past a signal which has been set against him and into a block in which another train is standing. These demands will undoubtedly be met by the statement that no wholly satisfactory apparatus has yet been produced, and the usual controversy may be expected

expected. As it may, the situation serves only to empha-size the fact that the installation of electric fraction upon main-line railways provides a method of control ling train movements wholly apart from the operations of individual engineers, and renders it possible to com-bine the action of danger signals with the electrical machiner; in such a manner that the mere act of sei-ting a signal against a train will also cut off the supply of current, and render any further progress impossible until the opening of the block also restores the motive

Even if there were no other advantages found in the use of electric traction, it would seem us if this opportunity of controlling the movement of trains thr tunity or controlling the movement or trains through the control of the supply of motive energy should be worthy of consideration. The New Haven road is already partially equipped with electric traction, and it is possible that the cost of completing this work, and combining it with some such system of automatic signal control would bear favorable comparison with the cost of permitting the continuation of the existing state of affairs.

### The Current Supplement

IN this week's issue of the SCENTIFIC AMERICAN SUF-PLEMENT there appears the first instalment of Sir Oliver Lodge's remarkable address before the Bri Onver Longes remarkable accress between the strings Association—Charles Dury writes on Timecta That Carry Disease."—The Preparation of an Aviation Map of the World is discussed.—An articulated carrowgage locomotive built for service in Tamania is illustrated and described.—M. N. Buckman reports on Progress in Egyptian Exploration.—A very fine Elephant Group, the work of the Scuiptor-Naturalist Carl E. Akeley, appears on the front cover, and a short article tells our readers about Akeley's work.—H. N. De Andrade writes on Lenhard's researches on phosphorescence.— The Practical Operation of Gas Engines With Blast Furnace Gas as Fuel is the subject of an important paper by Charles C. Sampson.

Emigration from the British Intented more and more to be to other parts of the empire, justice thin to foreign countries. Thus there has been a notable failing-off in emigration to the United States. The last annual report of the Emigrants' Information Office, insued at a parliamentary paper, states that or 28,156 latters received only 1.4 per cour related to the United States. As compared with the previous year, Inquiries conversing the United States decreased £4.6 per court. In-coinsection with the enigration or shalled showers to Canada, an interesting society has lately been found-off with beodynature at Wilmains, though a the Inquiries of the Inquiries and the Inquiries of the Inquiries and the Inquiries of the Inquiries o
